AN ASSESSMENT OF THE WATER QUALITY
OF THE WABASH RIVER BASIN
DERIVED FROM A BIOLOGICAL INVESTIGATION

INTRODUCTION

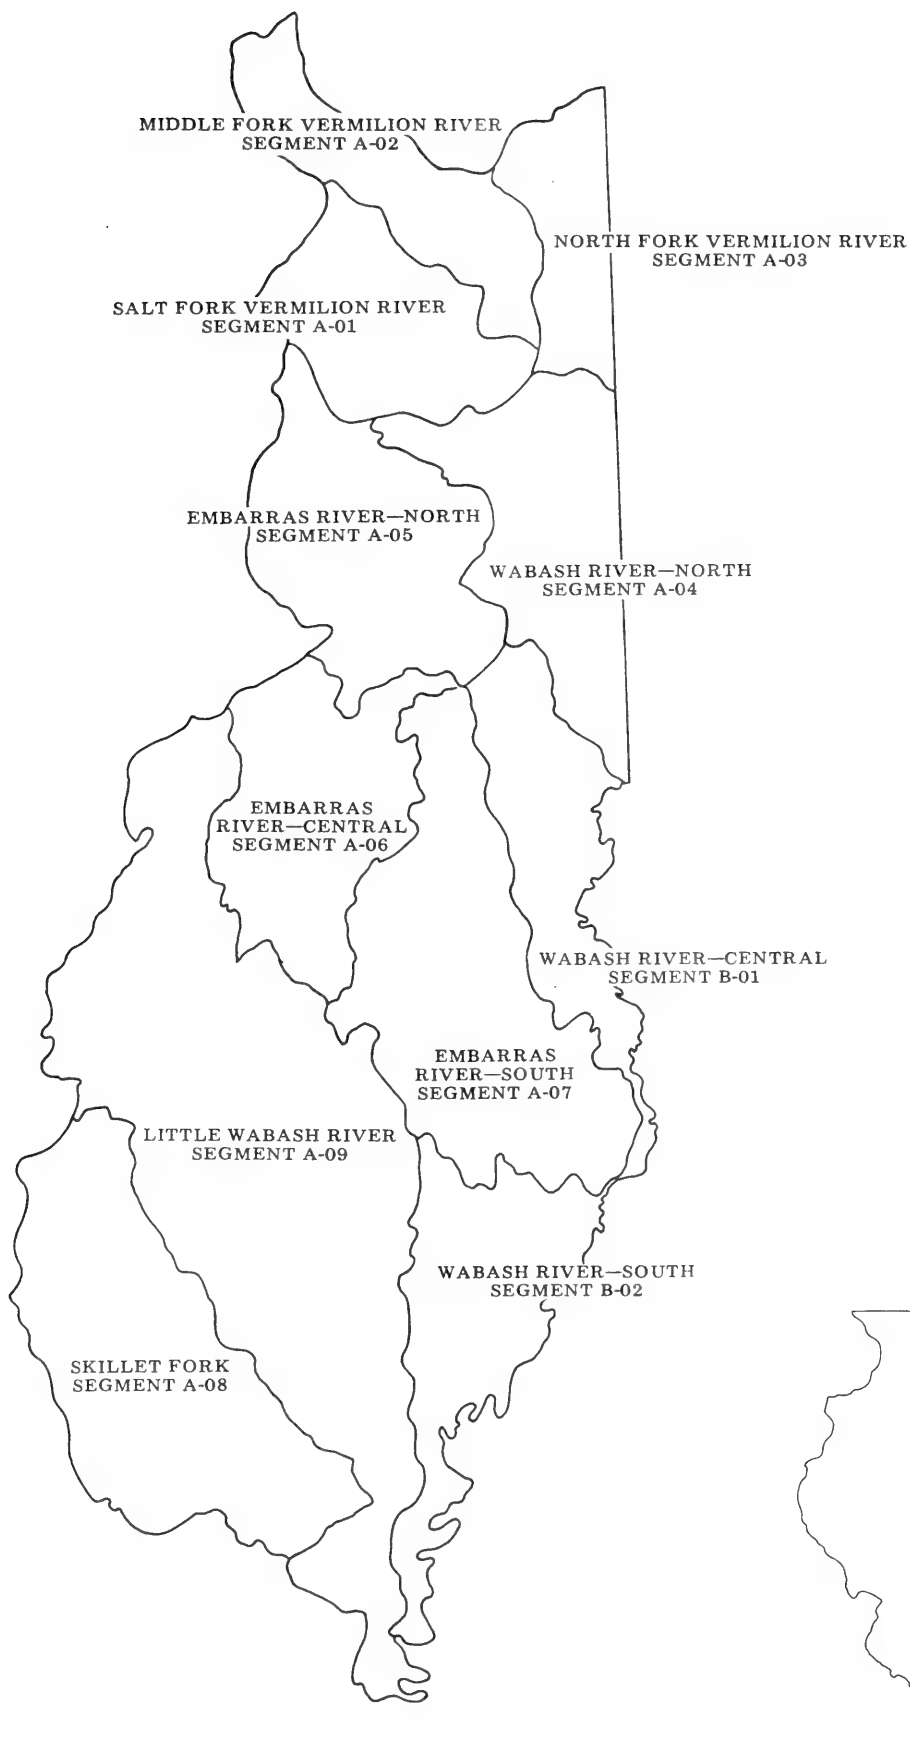

The benthic macroinvertebrate communities which develop at stream sites integrate factors such as climate, atmosphere, sun, lithography, topography, and urban, agricultural, and industrial activities. In turn, these govern inputs of nutrients, chemicals, allochthonous material, sediment, and other factors which affect the quality and quantity of runoff water entering stream systems (Karr and Gorman 1975).

Consequently, the composition of benthic macroinvertebrate communities is useful in evaluating long term changes in stream water quality resulting from a variety of man's activities including point sources of pollution from wastewater treatment plant effluents, industrial discharges, and some agricultural sources and non-point sources, both of which can change the structure of benthic communities.

Almost 900 sites were sampled in the Wabash River basin in southeastern Illinois (Fig. 1) to assess existing stream quality conditions based upon the composition of the benthic macroinvertebrate communities observed. Sampling was conducted during autumn, 1976, and spring and summer, 1977, to evaluate the effects of nearly 200 point sources upon benthic communities. Additional sampling was done to assess the effects of agricultural non-point sources of pollution and the presence of oil fields in the basin.

Figure 1. The Wabash River basin in Illinois, showing the designated Illinois Environmental Protection Agency stream segments.

WABASH RIVER BASIN

DESCRIPTION OF THE STUDY AREA

OVERVIEW

Location and topography. This survey documents existing stream conditions in the Wabash River basin, Illinois, based upon benthic macroinvertebrate communities. The Wabash River basin in Illinois is bounded on the north by the Kankakee River basin; on the east by the Indiana state line; on the south by the Saline River basin; and on the west from north to south by the Vermilion, Mackinaw, Sangamon, Kaskaskia, and Big Muddy River basins. The watershed in Illinois comprises nearly 2,280,000 ha, 15.8% of the total area of the state, and includes portions of 27 counties, as follows: Champaign, Clark, Clay, Coles, Crawford, Cumberland, Douglas, Edgar, Edwards, Effingham, Fayette, Ford, Franklin, Gallatin, Hamilton, Iroquois, Jasper, Jefferson, Lawrence, Marion, Moultrie, Richland, Shelby, Vermilion, Wabash, Wayne, and White. Drainage is into the Ohio River southeast of New Haven, Gallatin County, Illinois. In spite of the size of this watershed in Illinois, it is significant to note that the watershed includes an additional approximately 6,294,000 ha in Indiana and Ohio.

As with most river basins in Illinois, the physiography of the Wabash River basin reflects the Pleistocene history of the area. The Wabash River originates in the glacial lakes of northwestern Ohio and northern Indiana and flows west and southwest, reaching the Illinois state line southeast of Marshall. The entire course of the river is through the Till Plains Section of the Central Lowland Province. In its course along the eastern border of Illinois, it receives flow from the Bloomington Ridged Plain, the Springfield Plain, and finally, the Mt. Vernon Hill Country. The junction of the Wabash and Ohio Rivers delimits the Central Lowland Province from the Interior Low Plateaus Province. The entire watershed in Illinois drains deposits of the Illinoian glaciation. North of the northern border of Clark County, however, these deposits are overlain by more recent Wisconsinan deposits.

Geology. The original bedrock surface underlying the Wabash River basin is complex in the north. Silurian, Devonian, and Mississippian strata all break through the more recent Pennsylvanian strata in Champaign, Ford, Iroquois, and Vermilion Counties. The remainder of the watershed in Illinois is underlain by Pennsylvanian strata. Pennsylvanian rocks of the Caseyville, Abbott, and Spoon formations occur in Champaign and Vermilion Counties. To the south, these are replaced by the Carbondale and Modesto formations which follow the Wabash River valley to the mouth of the Embarras River in Lawrence County and form a ridge between the Embarras River and the North Fork of the Embarras River south to Crawford County. The remainder of the Wabash River basin in Illinois is underlain by the Bond and Mattoon formations of the Pennsylvanian strata. Pennsylvanian strata in parts of the watershed reach a depth of 615 m. Within this rock lie as many as 10 distinct strata of coal.

Climatology. Eastern and southeastern Illinois have a continental climate

with a wide range in temperature and frequent short-term fluctuations in temperature, humidity, cloudiness, and wind direction. Isotherms are, in general, from east to west indicating an increase in temperature from north to south. The difference in mean temperature between northern and southern portions of the watershed is less pronounced in summer than in winter. Isohyets are somewhat less regular than isotherms, but generally precipitation increases from north to south.

Climatological data from U. S. Weather Service stations in the Wabash River basin are summarized in Table 1. These data show a mean air temperature of 12.1 °C with extremes from -32 °C to 47 °C. The growing season varies from 164 to 190 days. Mean annual precipitation is 103.16 cm. This is concentrated in the growing season in the north, but distributed fairly evenly throughout the year in the south. September and October normally are the driest months. Mean annual snowfall is 38.8 cm.

The lakes and ponds of the northern part of the Wabash River basin usually are icebound from late December through early March. This is true also for most streams in the area. Ice cover ranges up to 30 cm. In the south, the depth of freeze in the soil averages about 15 cm, but during much of the average winter the ground and most lakes and ponds are not frozen. The rivers and streams also usually remain open during most of the winter.

Vegetation. A detailed classification of biotic provinces in Illinois was expressed by Vestal (1931) who based his divisions upon forest types of the original vegetative cover of the state. Four of his provinces occur within the Wabash River basin.

The *Grand Prairie Division* comprises all original prairie, except the sand areas, north of the southern limit of the Wisconsinan glaciation. This division includes the black-soil prairie surrounding the forested morainal hills in the northern part of the watershed. Intermorainal depressions contained marshes, lakes, and bogs. Large bunch grasses predominated in the prairie.

Bur oak was the predominant tree of the *Forests of the Grand Prairie Division*. Linden and red oak became frequent in mesic sites. Most of the older moraines in the southern part of this division are treeless, although it has been demonstrated that forest was much more extensive prior to prehistoric prairie fires.

The *Southern Division* was represented by the oldest area of Illinoian drift, exclusive of the loess-covered river borders. The original surface of this area was very flat, but due to its age, weathering, leaching, and stream erosion have affected greatly the character of the division. Vestal (1931) divided this division into three districts, two of which occur in the Wabash River basin. The Effingham District still represents the flat till-plain, while the McLeansboro District contains very little flat tableland. The landscape here is highly dissected by river bottomlands. Oak-hickory forest occurred throughout both districts, but black and sweet gum and the tulip tree also were represented in the McLeansboro District.

Table 1. Climatological data for 15 counties in the Wabash River basin, Illinois (period of record to date).

Location (county)	Temperature (°C)			Precipitation (cm)		Growing Season (days)
	Min.	Max.	Mean	Rainfall	Snowfall	
Champaign	-32	43	10.6	103.12	53.3	175
Clay	-	47	12.9	105.92	34.3	185
Coles	-31	43	12.1	96.24	43.2	178
Crawford	-29	46	12.7	104.44	38.1	186
Cumberland	-31	43	-	-	43.2	178
Edgar	-	-	11.9	100.02	-	-
Edwards	-	47	13.0	112.27	15.2	190
Hamilton	-30	45	13.8	107.95	26.7	189
Jasper	-	46	10.9	98.98	39.4	185
Lawrence	-	-	-	109.73	40.6	190
Richland	-	44	13.1	105.74	41.9	185
Vermilion	-30	44	11.1	95.99	50.8	164
Wabash	-	-	11.7	-	-	-
Wayne	-	-	13.3	93.66	39.4	188
White	-	-	-	105.08	-	-

The *Wabash Border Division* included the well-dissected belt of loess-covered hills west of the Wabash floodplain and the bottomlands themselves. The upland forests owe some of their distinctness to the absence of post and blackjack oak as well as to the presence of a few beech trees. The bottomlands contained luxuriant forests, including a number of southern plants such as the sweet gum, swamp oak, pecan, and tupelo.

It should be noted that Vestal (1931) was writing of original vegetative cover, much of which was altered even in his day. In spite of timber cutting, wetland drainage, and intensive agriculture, Smith (1961) found that the state's herpetofauna tended to coincide with Vestal's divisions. This implies an underlying influence of climatology, geography, and geology which transcends, in part, man-induced changes in vegetation and land use.

Population and land use. Most of the available population and land-use data are county-wide summaries. As such, these data reflect an area greater than the study area, but they are thought to be representative of the watershed. Data are available only for 21 of the 27 counties of the watershed. It is felt that means and percentages calculated from the 21-county data base are acceptable approximations of the entire 27-county area, but it is noted that four of the six "missing" counties are from the southern half of the river basin where the population is less dense and where mineral extraction activities represent a more significant role in the economy than in the predominantly agricultural areas to the north. The following are projections from the county-summary data provided by Fisher (1968, 1969a, 1969b, 1970a, 1970b, 1971), Lockhart (1968, 1969), Allen (1969, 1971), Horner (1969, 1970a, 1970b, 1970c, 1971a, 1971b, 1971c), Zebrun (1970), Fisher and Brown (1971a, 1971b), and Horner and Brummett (1972).

The principal early settlements of the Wabash River basin took place during the 18th century. These settlements expanded north along and west from the Wabash River. By 1820 this wave of settlers reached the northernmost portions of the watershed. The population of the area showed a fairly steady increase, especially during the oil boom of the early part of this century. The present population numbers about 5.7 million with a mean 10-year rate of decline of 3.6%. Population trends run from -12.3% (Edwards County) to +10.4% (Coles County), again based upon 10-year mean rates of change. In general, the southern counties are losing population and the northern ones are gaining. Population distribution ranges from 23% to 100% rural by county with a mean of 62% rural for the watershed. The population density ranges from 23.0 to 146.9 persons mi^{-1} with a mean of 49.1. The statewide average is just over 180 persons mi^{-1} .

Approximately 75% of the land in the Wabash River basin is agricultural. Corn, soybeans, and some wheat are the principal row crops. Live-stock operations, principally hogs, appear to be declining. Coal mining is important in the north and south. Oil production is especially important in the central part of the watershed.

STREAM SYSTEMS

Wabash River (B). Early French explorers named the Wabash or *Oubache*. It is one of the largest tributaries of the Ohio River, originating about 24 km east of the Indiana-Ohio state line at Lake St. Mary, Ohio. The Wabash flows in a northwesterly direction to the vicinity of Huntington, Indiana, then turns southwesterly until it empties into the Ohio River just north of Shawneetown, Illinois. The Wabash and its major tributaries (Salanomie, Mississinewa, White, Embarras, Little Wabash, and the Patoka Rivers) drain an area of approximately 8,572,900 ha, of which 2,279,200 ha are in Illinois. The Wabash is 760 km long with 320 km forming the boundary between Illinois and Indiana.

The topography in the Wabash River basin varies considerably from one area to the next. In the upstream portion, the land has a shallow rolling characteristic; toward the south it tends to be more broken as it approaches its confluence with the Ohio River. These regions correspond to the till plains of the Wisconsinian and Illinoian glaciations, respectively.

The Wabash River and most of the tributaries are low-gradient streams, not exceeding 0.19 m km^{-1} . Through the Grand Prairie Division, the river banks are typically vertical silt banks. The Wabash River is an order 8 stream at its confluence with the Ohio River. The drainage pattern is intermediate between a fully bifurcate dendritic pattern and a trellis pattern. The Wabash River is underdeveloped at all levels, except the order 7 level. It never reaches the potential order 14 stream of a fully bifurcate dendritic drainage pattern. Morphometric data (for Illinois only) are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	6,654	1.51	10,077.16
2	3,235	0.96	3,112.38
3	1,756	0.98	1,724.95
4	905	1.02	919.73
5	404	1.34	540.32
6	176	1.51	266.25
7	141	1.64	231.07
8	23	6.17	142.00
			TOTAL = 17,013.86

The major tributaries in Illinois are the Embarras River and the Vermilion River, both order 6 streams and the Little Wabash River, an order 7 stream, at their respective confluences with the Wabash River.

The soils of the Wabash River watershed were formed from loess deposited after the Wisconsinian glaciation. Alluvial material is present along the floodplains and river bottoms consist of sand, gravel, and rocks. There are 25 major soil associations present, formed from 42 separate elements. The associations and characteristics of the elements are listed below and will not be discussed in detail under each watershed subunit:

1. Cowden-Cisne,
2. Hosmer-Ava-Hickory,

3. Alford-Hickory,
4. Carmi-Sumner-Patton,
5. Wakeland-Petrolia-Darwin,
6. Stoy-Bluford-Blair,
7. Miami-Strawn-Camden,
8. Drummer-Flanagan,
9. Fincastle-Xenia,
10. Raub-Dana,
11. Sabina-Starks,
12. Sawmill-Huntsville,
13. Elliott-Swygert,
14. Proctor-Brenton,
15. Hosmer-Hickory,
16. Camden-Starks,
17. Russell-Strawn,
18. Miami-Russell-Fincastle,
19. Catlin-Sidell,
20. Lawson-Strawn,
21. Brenton-Drummer,
22. Ashkum-Elliott-Andres,
23. Elliott-Varna,
24. Boyce-Swygert,
25. Blount-Morley.

Alford is a loess soil described from Iowa. It is deep, light-colored, and medium to high in natural productivity.

The *Andres* series consists of somewhat poorly drained soils that have slopes of less than 3% on uplands. The surface layer is a black silt loam. The subsoil is a mottled dark grayish-brown clay loam in the upper part and silty clay loam in the lower part. The underlying material is silty clay loam, till, or lakebed sediments. Andres soils have a high organic matter content in the surface layer, moderate permeability in the subsoil, and a high available water capacity. Surface water runoff is slow to medium.

The *Ashkum* series consists of poorly drained soils that have slopes of less than 2% on uplands. They have a black silty clay loam surface layer. The subsoil is a mottled olive-gray silty loam. The underlying material is silty clay loam glacial till. Ashkum soils have a high organic content in the surface layer, moderately slow permeability in the subsoil and a high available water capacity. Surface water runoff is slow.

Ava silt loam is a light-colored, strongly developed soil usually found on slopes of 3% to 7%. It was developed under timber vegetation, from 0.5 to 1.3 m of loess on Illinoian drift. Ava is slowly to moderately permeable to the passage of air and water. It is moderately well drained. It has some fragipan formation which hinders deep root penetration. Major problems are fertility and erosion control. This soil is moderately productive under a high level of management.

Blair is an upland soil subject to slight to severe erosion on gentle to strong slopes, but with some level areas subject to wetness. The soil is deep to moderately deep, light-colored, and low to medium in natural

productivity.

The *Blount* series consists of somewhat poorly drained soils that have slopes of less than 5% on uplands. They have a dark grey silt loam surface layer. The subsoil is mottled light brownish-gray and yellowish-brown silty clay loam and silty clay. The underlying material is silty clay loam till. Blount soils have a low organic matter content in the surface layer, slow permeability in the subsoil, and a high available water capacity. Surface water runoff is medium to slow.

Bluford silt loam is a light-colored, strongly developed soil formed under timber vegetation from 0.5 to 1.3 m of Illinoian drift. It occurs on slopes of 1% to 4% and is slowly permeable to air and water. Bluford is imperfectly drained and has some fragipan development which inhibits deep root penetration. Tiles do not function satisfactorily in this soil. Major problems are fertility, drainage, and erosion control.

Brenton is a deep prairie soil and occurs on level to gently sloping areas. Water moves freely through this soil. The water supplying capacity and natural productivity are high. Brenton is formed from medium-textured, water-deposited, outwash material.

Bryce series soils include very poorly drained soils having slopes of less than 2% on uplands. The surface layer is black silty clay. The subsoil is a mottled olive-grey silty clay. The underlying material is silty clay. Bryce soils have a high organic matter content in the surface layer, high available water capacity, and slow permeability. Surface water runoff is slow.

Camden silt loam is a deep, light-colored timber soil occurring on slopes ranging from 2% to 5%. It is well-drained with good air and water movement through the soil. It has high water-supplying capacity and productivity is moderate to high. Natural fertility is low. This soil has developed in 0.6 to 1.0 m of silty material overlying water-deposited layers of silts, loams, sands, and occasional gravels. Gravel often occurs below the 1.5-m depth.

A terrace and upland soil subject to wetness on some level areas, *Carmi* soils are subject to droughtiness and wind erosion on sandy areas and slight to severe water erosion on gentle to moderate slopes. The soils are deep, light- to dark-colored, and low to high in natural productivity.

Catlin silt loam is a deep, dark-colored upland prairie soil occurring on slopes ranging from 2% to 12%. This soil is naturally well drained and air and water move freely through it. It has a high water supplying capacity. Catlin has formed in 1 to 1.6 m of silty loess over calcareous loam textured till.

Cisne silt loam is a deep, moderately dark-colored prairie soil usually found on slopes of 0% to 2%. It developed from 0.8 to 1.3 m of loess on weathered Illinoian till. This soil is strongly developed and acid. It is poorly drained with slow to very slow permeability. Tiles do not function satisfactorily in this soil. Plant roots penetrate the subsoil well, however.

Cowden silt loam is a deep, moderately dark-colored upland prairie soil usually found on slopes of 1% to 3%. It developed under grassland vegetation in 1.3 to 2 m of loess on weathered Illinoian till. The soil is acid and strongly developed. It is slowly permeable to water and poorly drained. Major problems are fertility, erosion control, and drainage.

Dana is a moderately well-drained upland prairie soil usually occurring on slopes of 2% to 7%. It has a high water supplying capacity and is highly productive when properly managed. Air and water move freely through this soil. It was formed from 0.5 to 1 m of loess over till.

Darwin is a bottomland soil subject to flooding. Wetness or droughtiness are problems in some parts of the area. The soils are deep, light- to dark-colored, and low to high in natural productivity.

Drummer silty clay loam is a deep, dark-colored prairie soil occurring on level to slightly depressed areas. It is naturally poorly drained and has a high water supplying capacity. The water table may be at or near the surface during parts of the year. The rate of water movement through the soil is good, when drained, and natural productivity is high. Drummer has developed in medium textured (silty or loamy) glacial material.

Elliott is an upland prairie soil occurring on slopes of 1% to 6%. Plant roots penetrate the till with difficulty. If this soil has not been drained, the water table may be too high during part of the year. It has rather slow underdrainage. The water supplying capacity is high. Elliott is formed from calcareous silty clay loam till.

Fincastle is a light-colored soil with a mottled, brown and gray silty clay loam subsoil and a clay loam lower subsoil containing some pebbles. Below 1 m, the soil consists of calcareous loamy material. Permeability is moderate and available moisture capacity is high.

Flanagan silt loam is a deep, dark-colored upland prairie soil usually occurring on slopes of 0% to 4%. If this soil has not been drained, the water table may be high during wet seasons. Air and water move freely through this soil. The water supplying capacity and natural productivity are high. Flanagan was formed from 1 to 1.5 m of silty loess over calcareous loam or silty clay loam textured till.

Hickory gravelly loam is an eroded, light-colored timber soil usually found on slopes of 15% to 30%. This soil developed from till. It is moderate to moderately slow in its permeability to water.

Hosmer silt loam is a deep, light colored, strongly developed timber soil, formed from 1.5 to 3 m of loess on Illinoian drift or from 2 m of loess over bedrock. This soil is generally moderately well-drained. It is moderately slow to slowly permeable and the fragipan resists root penetration.

Huntsville is a deep, dark brown to black soil which is a water deposited floodplain soil. It is highly productive.

Lawson is a deep, dark-colored bottomland soil. It has not been

drained and the water table is usually high during the wetter parts of the year. Air and water move freely through this soil. The available water-holding capacity and natural productivity are high.

Miami is a naturally well-drained, light-colored timber soil usually occurring on slopes from 2% to 12%. Air and water move freely in this soil and it has no obstruction to deep root growth. It has a high water supplying capacity. It was formed from calcareous loam-textured till.

The *Morley* series consists of moderately well-drained soils that have 2% to 30% slopes on uplands. They have a dark grayish-brown silt loam surface layer and a brown silty clay subsoil. The underlying material is silty clay loam till. Morley soils have a low organic matter content and a high available water capacity. Surface water runoff is medium to very rapid.

Patton is a deep, moderately dark-colored soil occurring on level to very gently sloping terrace positions. If this soil is not drained, the water table is high during much of the year. Water moves through this soil at a moderate to moderately slow rate. It has a high water-holding capacity. Patton is formed from lakebed sediments.

Petrolia is a bottomland soil subject to flooding. Wetness or droughtiness are problems in some parts of the area. The soil is deep, light- to dark-colored, and low to high in natural productivity.

Proctor is a very dark prairie soil, developed from water deposited glacial outwash. It occurs on level to gently sloping areas. Water and air move freely through it and it is high in natural productivity. On the slope, this soil has good natural drainage, but requires erosion control. On the level, artificial drainage is required.

Raub is a deep, upland prairie soil usually occurring on slopes of 0% to 4%. If this soil has not been drained, the water table may be high during wet seasons. It has a high water-supplying capacity and it is highly productive when properly managed. Air and water move freely through this soil. It has formed from 0.5 to 1 m of loess over till.

Russell silt loam is an upland timber soil usually occurring on slopes from 3% to 12%. It is naturally well-drained and air, water, and roots move freely through the soil. It has a high water-supplying capacity. It has formed from 0.5 to 1 m of loess over loam-textured till which is calcareous below 1.3 to 1.6 m.

Sabina silt loam is a deep, light-colored timber soil usually occurring on slopes from 0% to 3%. Some areas may require drainage due to the seasonally high water table. Air and water move rather slowly through this soil, but it has no obstruction to deep root growth. This soil has a high water-supplying capacity. Sabina has formed in 1.3 to 1.6 m of loess over calcareous loam-textured glacial till.

Sawmill is a deep, dark-colored bottomland soil. It has a high water table during the wet seasons unless it has been artificially drained. Air, water, and roots move freely through this soil. It has a high water-

supplying capacity. Sawmill has developed in medium to heavy water deposited sediments.

Sidell is a naturally well-drained upland prairie soil usually occurring on slopes from 3% to 12%. It has a high water-supplying capacity and is highly productive when properly managed. It has formed from 0.5 to 1 m of loess over till.

Stoy silt loam is a deep, light-colored timber soil usually occurring on slopes from 1% to 4%. It has developed 1.3 to 3 m of loess over Illinoian till or 2 m of loess over bedrock. This soil may have fragipan development which restricts air and water movement and root penetration. It is imperfectly drained. Fertility is a major problem.

Starks silt loam is a deep, light-colored timber soil occurring on level to gently sloping areas. It is poorly drained, with a high water-supplying capacity. If the soil has not been drained, the water table may be high during parts of the year. The rate of water movement through the soil is rather low and the productivity is moderate. There are no obstructions in this soil which hinder deep root growth. Starks has developed in 0.6 to 1 m of silty material overlying water-deposited layers of silt, loams, sands, and occasional gravels. Gravel often occurs below the 1.5-m depth.

Strawn is a light-colored upland timber soil usually occurring on slopes ranging from 5% to 25%. It is naturally well-drained and air, water, and roots move freely through it. Its water-supplying capacity is slightly inadequate and it is moderately productive when properly managed. It is formed from calcareous loam-textured till.

Summer is a terrace and upland soil which is subject to wetness on some level areas, droughtiness, wind erosion, sandy areas, and slight to severe water erosion on gentle to moderate slopes. This soil is deep, light to dark in color and low to high in natural productivity.

Swygert is a deep, dark-colored soil with a mottled gray and brown silty clay and clay subsoil that contains some sand and pebbles. It is occasionally wet unless artificially drained. Permeability is slow and available moisture capacity is high.

Varna is a deep, dark-colored upland prairie soil developed from medium-textured material less than 0.6 m thick on silty clay loam till which becomes calcareous at less than 1 m. It is usually found on 3% to 10% slope. It is moderately slow in permeability and has good resistance to drought. Erosion is a problem on this soil.

Wakeland silt loam is a deep, dark-colored bottomland soil usually found on slopes of 0% to 1%. It is moderately permeable to water and air movement. The main problems are fertility, drainage, overflow, and weed control. This soil is highly productive under a high level of management.

Xenia silt loam is an upland timber soil usually occurring on slopes from 1% to 5%. It is moderately well-drained and is usually not wet except for short periods of heavy rainfall. Air, water, and roots move freely

through the soil. It has a high water-supplying capacity and is very productive when properly managed. Xenia has formed from 0.5 to 1 m of loess over loam-textured till which becomes calcareous at about 1.3 m.

French Creek (BB). French Creek is located within White and Edwards Counties, Illinois, and empties into the Wabash River approximately 4 km south of Grayville. French Creek flows in a general southerly direction and drains an area of approximately 5,957 ha. It is a low-gradient stream (2.66 m km^{-1}).

The major tributary of French Creek is Onion Creek, also a low-gradient stream (1.32 m km^{-1}). French Creek is an order 4 stream at its confluence with the Wabash River. The drainage pattern is trellis-like. French Creek is overdeveloped at the order 1 and order 2 levels and underdeveloped at the order 3 level. It never reaches the potential order 6 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	34	1.12	37.90
2	23	0.76	17.40
3	5	0.82	4.10
4	4	1.12	4.50
			Total = 63.90

Onion Creek is an order 2 stream at its confluence with French Creek.

The soil of the French Creek watershed consists predominantly of silt and sand.

Bonpas Creek (BC). Bonpas Creek is the common boundary between Edwards and Wabash Counties, Illinois. French traders named this stream *Bon Pas*, meaning "good passage" as the Indians were friendly and their trip to the trading post at Vincennes was nearly complete. It originates east of Olney in Richland County and empties into the Wabash River near Grayville. Bonpas Creek drains 66,822 ha and is 72 km long. The major tributaries of Bonpas Creek include Crooked Creek, Little Bonpas Creek, Walzer Creek, Buck Creek, Indian Creek, and Mud Creek.

Bonpas Creek is a low-gradient stream (0.2 m km^{-1}) which reaches order 5 before its confluence with the Wabash River. The drainage pattern is intermediate between a fully bifurcate dendritic pattern and a trellis pattern. Bonpas Creek is underdeveloped at the order 1, 2, and 4 levels and overdeveloped at the order 3 and 5 levels. It never reaches the potential order 10 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	458	1.36	622.90
2	228	0.78	177.10
3	135	0.63	84.80
4	49	0.96	47.00
5	39	1.18	46.20
			Total = 978.00

All major tributary streams are order 3 streams at their confluences with Bonpas Creek with the exception of Little Bonpas Creek, an order 4 stream.

Wisconsinan silt covers most the the Bonpas Creek watershed to a depth varying between 0.6 to 1.3 m. The creek valley is composed of relatively young alluvial material from melt waters of the Wisconsinan glacier overlying older Illinoian deposits.

Six soil associations are present, as follows: Cowden-Cisne, Hosmer-Ava-Hickory, Alford-Hickory, Carmi-Summer-Patton, Wakeland-Petrolia-Darwin, and Stoy-Bluford-Blair.

The stream has a mud bottom and is usually silt laden due to agricultural activity in the watershed. A potential source of pollution is the oil field south of Albion.

Coffee Creek (BD). Coffee Creek is located entirely within Wabash County, Illinois, and empties into the Wabash River close to Coffee Island north of Rochester, Illinois. Coffee Creek flows in a southeasterly direction and drains an area of approximately 6,216 ha. It is a low-gradient stream (1.42 m km^{-1}).

The major tributary of Coffee Creek is Sugar Creek, an order 2, medium-gradient stream (4.88 m km^{-1}). Coffee Creek is an order 4 stream at its confluence with the Wabash River. The drainage pattern is trellis-like. Coffee Creek is overdeveloped at all levels and never reaches the potential order 6 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	47	1.07	50.20
2	19	0.76	14.40
3	10	0.66	6.60
4	14	0.79	11.00
			Total = 82.20

Most of the channel of Coffee Creek and its tributaries has been dredged, a process which severely reduces habitat diversity. The lower-most reaches of the stream, however, remain unchannelized and flow through forest. Virtually the entire watershed of Coffee Creek is within oilfields. Thus, the potential for pollution from this source is great.

Embarras River (BE). The Embarras River originates in Champaign County and extends southeastward through Douglas, Edgar, Coles, Cumberland, Clark, Effingham, Jasper, Crawford, Richland, and Lawrence Counties, Illinois. It empties into the Wabash River north of St. Francisville. The Embarras River is approximately 211 km long and drains an area of 595,700 ha. One lake of 145 ha is located on the main stream at Charleston (Coles County).

The Embarras River is a low-gradient stream (0.37 m km^{-1}). Major tributaries of the Embarras River include Muddy Creek (1.08 m km^{-1}), Crooked Creek (2.69 m km^{-1}), Hurricane Creek (1.51 m km^{-1}), Little Embarras River (0.72 m km^{-1}), and the North Fork of the Embarras River (0.19 m km^{-1}). All but the North Fork are medium-gradient streams.

The Embarras River is an order 6 stream at its confluence with the Wabash River. The drainage pattern is intermediate between a fully bifurcate dendritic pattern and a trellis pattern. The Embarras River is underdeveloped at the order 1 and 2 levels and overdeveloped at the order 3, 4, 5, and, especially, order 6 levels. It never reaches the potential order 12 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	1,943	1.47	2,850.60
2	903	0.94	847.55
3	523	1.00	523.28
4	278	0.88	243.22
5	133	1.16	153.92
6	109	1.35	146.77
			Total = 4,765.34

Hurricane Creek, Crooked Creek, and the Little Embarras Creek are order 4 streams and Muddy Creek and the North Fork of the Embarras River are order 5 streams at their confluences with the Embarras River.

The soils of the Embarras River watershed were formed by Wisconsin loess varying from 60 cm to 150 cm on the uplands and from alluvial material along the floodplain. Thirteen soil associations are known from the basin including: Wakeland-Petrolia-Darwin, Carmi-Sumner-Patton, Alford-Hickory, Stoy-Bluford-Blair, Cowden-Cisne, Miami-Strawn-Camden, Drummer-Flanagan, Fincastle-Xenia, Raub-Dana, Sabina-Starks, Sawmill-Huntsville, Elliott-Swygert, and Proctor-Brenton. The properties of these soils have been described above.

Oil fields are common in the Embarras River basin downstream from Charleston and are especially common west of Robinson in Crawford County. Extraction, storage, transport, and refining operations all entail a certain risk to water quality and portions of the basin have a history of oil-related pollution.

Sugar Creek (BF). Sugar Creek is located entirely within Crawford County, Illinois, and empties into the Wabash River just southwest of Palestine,

Illinois. Sugar Creek flows generally in a southeasterly direction and drains an area of approximately 16,317 ha. It is a medium-gradient stream (2.76 m km^{-1}).

The major tributary of Sugar Creek is Lamotte Creek, also a medium-gradient stream (1.81 m km^{-1}). Sugar Creek is an order 4 stream at its confluence with the Wabash River. The drainage pattern is trellis-like. Sugar Creek is underdeveloped at the order 1 level and overdeveloped at the order 4 level. It never reaches the potential order 7 stream of a fully bifurcate dendritic drainage pattern. Most of the length of the lower half of Sugar Creek is confined within levees. Morphometric data are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	57	1.67	95.27
2	30	1.09	32.83
3	13	1.21	15.80
4	13	0.74	9.60
			Total = 153.50

Lamotte Creek is an order 4 stream at its confluence with order 3 Sugar Creek. Thus, while Lamotte Creek has a smaller watershed than Sugar Creek, the drainage system is more fully bifurcate and reaches a higher stream order.

The soil associations of the Sugar Creek watershed are Wakeland-Petrolia-Darwin, Carmi-Sumner-Patton, and Alford-Hickory. The properties of these soils have been described above.

Raccoon Creek (BG). Raccoon Creek is located within Crawford and Clark Counties, Illinois, and empties into the Wabash River just north of Hutsonville, Illinois. Raccoon Creek flows in a southeasterly direction and drains an area of approximately 12,432 ha. It is a medium-gradient stream (2.64 m km^{-1}).

Tributaries of Raccoon Creek include the North and South Fork, both order 3 streams at their confluences with Raccoon Creek. Raccoon Creek is an order 4 stream at its confluence with the Wabash River. The drainage pattern is intermediate between a fully bifurcate dendritic pattern and a trellis pattern. Raccoon Creek is overdeveloped at the order 3 and 4 levels and never reaches the potential order 6 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	38	1.32	50.00
2	18	1.25	22.50
3	12	1.35	16.25
4	7	0.71	5.00
			Total = 93.75

The soil associations of the Racoon Creek watershed include Wakeland-Petrolia-Darwin, Carmi-Sumner-Patton, and Alford-Hickory. The properties of these soils have been described above.

Mill Creek (BH). Mill Creek is located entirely within Clark County, Illinois, and empties into the Wabash River just east of York. Mill Creek flows in a general southeasterly direction and drains an area of approximately 27,454 ha. It is a medium-gradient stream (1.92 m km^{-1}).

Major tributaries of Mill Creek are East Mill Creek, Hurricane Creek, and Joes Fork, all medium-gradient streams (2.18 , 4.36 , and 2.99 m km^{-1} , respectively). Joes Fork is an order 3 stream and Hurricane and East Mill Creeks are order 4 streams at their confluences with Mill Creek.

Mill Creek is an order 5 stream at its confluence with the Wabash River. The drainage pattern is trellis-like. Mill Creek is underdeveloped at all levels except the order 5 level. Order 5 is highly overdeveloped. Mill Creek never reaches the potential order 9 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	215	1.12	239.95
2	101	0.65	65.67
3	53	0.61	32.23
4	24	0.64	15.32
5	36	0.78	28.00
			Total = 381.17

The soil associations of the Mill Creek watershed include Wakeland-Petrolia-Darwin, Carmi-Sumner-Patton, and Alford-Hickory. These soils have been described above.

Most of the tributaries of Mill Creek flowing from the west cut steep valleys as they drop from the uplands to the floodplain of Mill Creek. These streams often have bedrock and cobble riffles, an unusual aquatic habitat in east-central Illinois. Thus, many of these streams support a diverse and uncommon biota.

Sugar Creek (BI). Sugar Creek is located entirely within Clark County, Illinois, and empties into the Wabash River approximately 2 km north of Darwin. Sugar Creek flows in a general southeasterly direction and drains an area of approximately 6,216 ha. It is a high-gradient stream (4.03 m km^{-1}).

Major tributaries of Sugar Creek include Martin Branch, Partridge Creek, and Neely Creek, also high-gradient streams (5.64 , 3.23 , and 2.98 m km^{-1} , respectively). Sugar Creek is an order 4 stream at its confluence with the Wabash River. Its major tributaries Sugar Creek, Martin Branch, and Partridge Creek are order 2 streams and Neely Creek an order 3 stream

at their respective confluences with Sugar Creek.

The drainage pattern of Sugar Creek is trellis-like, overdeveloped at the order 1 and 2 levels, and underdeveloped at the order 4 level. It never reaches the potential order 6 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	47	1.25	58.80
2	35	0.90	31.40
3	7	0.77	5.40
4	2	0.70	1.40
			Total = 97.00

The soil associations of the Sugar Creek watershed include Wakeland-Petrolia-Darwin, Carmi-Sumner-Patton, and Alford-Hickory. These soils have been described above.

Big Creek (BJ). Big Creek is located in Edgar and Clark Counties, Illinois, and empties into the Wabash River approximately 7 km north of Darwin. Big Creek flows in a general southeasterly direction and drains an area of approximately 24,346 ha. It is a medium-gradient stream (2.13 m km^{-1}).

The two major tributaries of Big Creek, Little Creek and West Fork of Big Creek, are high- to medium-gradient streams (2.97 and 2.16 m km^{-1} , respectively). Little Creek is an order 3 stream and West Fork an order 4 stream at their respective confluences with Big Creek.

Big Creek is an order 4 stream at its confluence with the Wabash River. The drainage pattern is trellis-like. Big Creek is overdeveloped at the order 1 level and order 4 level and never reaches the potential order 8 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	141	1.32	186.47
2	65	0.78	50.65
3	35	0.80	27.92
4	39	0.61	23.80
			Total = 288.84

The soils of the Big Creek watershed occur in four major associations: Hosmer-Hickory, Camden-Starks, Russell-Strawn, and Miami-Russell-Fincastle. The characteristics of these soils have been described above.

Ashmore Creek (BK). Ashmore Creek is located within Clark County, Illinois, and empties into the Wabash River approximately 4 km north of Hutton, Indiana. Ashmore Creek flows in a general southeasterly direction and

drains an area of approximately 2,072 ha. It is a high-gradient stream (2.90 m km^{-1}).

Ashmore Creek has no major tributaries and is an order 3 stream at its confluence with the Wabash River. The drainage pattern is a well-developed trellis pattern, underdeveloped at the order 1 and 2 levels and overdeveloped at the order 3 level. It never reaches the potential order 5 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	13	1.46	19.00
2	6	1.43	8.60
3	6	1.07	6.40
			Total = 34.00

Soil associations of the Ashmore Creek watershed include Hosmer-Hickory, Camden-Starks, Russell-Strawn, and Miami-Russell-Fincastle.

Clear Creek (BL). Clear Creek is located in Clark and Edgar Counties, Illinois, and Vigo County, Indiana. It leaves Illinois in Clark County and empties into the Wabash River just south of the Terre Haute Federal Penitentiary, Indiana. Clear Creek flows in a general southeasterly direction and drains an area of approximately 7,252 ha in Illinois. It is a high-gradient stream (3.48 m km^{-1}).

The major tributaries of Clear Creek are Mud Creek and the South Branch of Clear Creek. Mud Creek is an order 3 stream at its confluence with Clear Creek, the South Fork of Clear Creek an order 2 stream. Clear Creek is an order 4 stream at its confluence with the Wabash River. The drainage patterns are trellis-like. Clear Creek is underdeveloped at the order 3 level and overdeveloped at the order 1, 2, and 4 levels. It never reaches the potential order 6 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows (for Illinois only):

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	43	1.52	65.42
2	18	1.05	18.95
3	6	1.03	7.20
4	13	0.80	10.40
			Total = 101.97

The soils of the Clear Creek watershed represent four major associations: Camden-Starks, Miami-Russell-Fincastle, Hosmer-Hickory, and Russell-Strawn.

The headwaters of the Clear Creek system drain the face of the Shelbyville moraine. Thus, gradient here is high. The stream does not maintain a permanent flow until Mud Creek joins Clear Creek just upstream from the Clark-Edgar County line.

Sugar Creek (BM). Sugar Creek is located in Edgar County, Illinois, and Vigo County, Indiana. It empties into the Wabash River just south of Terre Haute, Indiana. Sugar Creek flows in a general southeasterly direction and drains an area of approximately 15,540 ha within Illinois. In the upstream portion of the drainage basin, Sugar Creek has a rather steep gradient and has carved a deep valley through the Shelbyville moraine. On the average, however, Sugar Creek is a medium-gradient stream (1.89 m km^{-1}).

The major tributary of Sugar Creek is Little Sugar Creek, an order 3 stream, which flows through Indiana for most of its course. Sugar Creek is an order 4 stream at its confluence with the Wabash River. The drainage pattern is a well-developed trellis pattern. Sugar Creek is overdeveloped at all levels and never reaches the potential order 6 stream of a fully bifurcate dendritic drainage pattern. Morphometric data (for Illinois only) are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	44	1.86	82.00
2	21	1.03	21.57
3	18	0.95	17.18
			Total = 120.75

A series of dams in the headwaters of Sugar Creek has produced Twin Lakes on the north edge of Paris, Illinois. These lakes have a total surface area of approximately 66 ha. Effluent from the Paris wastewater treatment plant enters Sugar Creek immediately downstream from the dam of East Lake and has caused a number of fish kills in the creek.

Brouilletts Creek (BN). Brouilletts Creek is located in Edgar and Vermillion Counties, Illinois, and Vermillion County, Indiana. It empties into the Wabash River approximately 3 km east of Shepardsville, Indiana. Brouilletts Creek flows in a general southeasterly direction and drains an area of 79,521 ha in Illinois and Indiana. Of these, 75,151 ha lie in Illinois. Brouilletts Creek is a low-gradient stream (0.74 m km^{-1}).

The major tributaries of Brouilletts Creek are its North and South Forks, both medium-gradient streams (1.19 and 2.06 m km^{-1} , respectively). Brouilletts Creek is an order 5 stream at its confluence with the Wabash River. The South Fork is an order 3 and the North Fork an order 4 stream at their respective confluences with Brouilletts Creek. The drainage pattern is intermediate between a fully bifurcate dendritic pattern and a trellis pattern. Brouilletts Creek is overdeveloped at all levels, except the order 5 level. It never reaches the potential order 7 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows (for Illinois only):

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	89	2.24	199.17
2	45	1.90	85.42
3	22	1.82	40.00

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
4	18	1.57	28.33
5	2	1.87	3.75
			Total = 356.67

Four major soil associations occur in the watershed, including Drummer-Flanagan, Miami-Russell-Fincastle, Flanagan-Drummer, and Russell-Strawn. The properties of these soils have been summarized above.

The Brouilletts Creek watershed is separated from the Little Vermilion River watershed to the north by a moraine of the Wisconsinan glaciation. The general elevation of the land south of the moraine is approximately 7 m lower than that north of the moraine.

Little Vermilion River (BO). The Little Vermilion River flows through Champaign and Vermilion Counties, Illinois, and Vermillion County, Indiana. It enters the Wabash River near Newport, Indiana. The Little Vermilion River flows in an easterly direction and drains an area of approximately 30,303 ha. It is a low-gradient stream (0.53 m km^{-1}).

The Little Vermilion River receives numerous tributaries flowing in from the moraine to the south. Most of these are small order 1 and 2 streams. The Little Vermilion River is an order 4 stream at its confluence with the Wabash River. The drainage pattern is intermediate between a fully bifurcate dendritic pattern and a trellis pattern. The Little Vermilion River is overdeveloped at all levels, especially the order 4 level. It never reaches the potential order 7 stream of a fully bifurcate dendritic drainage pattern. Morphometric data (for Illinois only) are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	70	1.86	130.28
2	34	1.49	50.73
3	17	1.76	30.00
4	17	0.98	16.67
			Total = 227.68

The soil associations present in the Little Vermilion River basin include Drummer-Flanagan, Catlin-Sidell, Fincastle-Russell, and Lawson-Strawn. The properties of these soils have been discussed above.

Most of the upstream portion of the Little Vermilion River has developed on a flat glacial lake bed north of a moraine of the Wisconsinan glaciation. Thus, tributaries from the south have higher gradients than those from the north. The Little Vermilion River does not develop much of a valley until it reaches the vicinity of Georgetown.

Vermilion River (BP). The Vermilion River originates in Ford and Iroquois

Counties, Illinois. The confluence of the Middle and Salt Fork Rivers in Catlin Township, Champaign County, Illinois, forms the Vermilion River proper. A third major branch, the North Fork, joins the river south of Danville. The Vermilion River flows through Vermilion County and empties into the Wabash River near Cayuga, Vermillion County, Indiana. The Vermilion River flows in a general southeasterly direction and drains an area of approximately 340,067 ha. It is a low-gradient stream (0.61 m km^{-1}).

The major tributaries of the Vermilion River, the Middle Fork, Salt Fork, and North Fork Rivers, are low-gradient streams (0.78 , 0.45 , and 0.96 m km^{-1} , respectively). The drainage pattern is intermediate between a fully bifurcate dendritic pattern and a trellis pattern. The Vermilion River in Illinois is overdeveloped at all levels, except the order 6 level. It never reaches the potential order 10 stream of a fully bifurcate dendritic drainage pattern. The Middle Fork River is an order 4 stream and both the Salt Fork and North Fork Rivers are order 5 streams at their confluences with the Vermilion River. Morphometric data are summarized for the Vermilion River as follows (for Illinois only):

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	595	1.92	1,144.37
2	273	1.20	327.73
3	139	1.32	183.42
4	117	1.32	154.62
5	47	2.10	98.80
6	12	1.87	22.40
			Total = 1,931.34

The soils of the Vermilion River basin represent nine major associations: Drummer-Flanagan, Catlin-Sidell, Brenton-Drummer, Ashkum-Elliott-Andres, Elliott-Varna, Bryce-Swygert, Fincastle-Russell, Blount-Morley, and Lawson-Strawn. The properties of these soils have been discussed above. It is significant to note that these glacial soils have a high carbonate-bicarbonate level. Thus, the waters of the Vermilion River are well-buffered. The extensive strip mining activities have not produced acid mine pollution in the watershed, probably because of this buffering capacity.

Little Wabash River (C). The Little Wabash River originates near Mattoon, Coles County, Illinois, in the area of the terminal moraine of the Wisconsin glacier. Following a southeasterly meandering course, the river flows through portions of nine Illinois counties: Clay, Cumberland, Edwards, Effingham, Gallatin, Jasper, Richland, Wayne, and White. The Little Wabash River empties into the Wabash River 3 km south of New Haven in White County. The main stream is approximately 384 km long and drains an area of 1,100,750 ha.

The principal tributary in the Little Wabash drainage basin is Skillet Fork. This stream originates in Marion County and empties into the Little Wabash approximately 4 km northeast of Carmi. The other major tributaries are the Fox River and Muddy Creek. All three streams have low gradients.

The Little Wabash River is an order 7 stream at its confluence with the Wabash River. Skillet Fork is an order 6, the Fox River an order 5, and Muddy Creek an order 4 stream at their respective confluences with the Little Wabash River. The drainage pattern of the Little Wabash system is intermediate between a fully bifurcate dendritic pattern and a trellis pattern. The Little Wabash is overdeveloped at all levels, except the order 6 level and never reaches the potential order 12 stream of a fully bifurcate dendritic drainage pattern. Morphometric data are summarized as follows:

<u>Order</u>	<u>Number Links</u>	<u>Mean Length (km)</u>	<u>Total Length (km)</u>
1	2,382	1.55	3,682.50
2	1,186	0.95	1,128.48
3	637	0.93	595.45
4	287	1.11	318.07
5	147	1.43	209.65
6	55	1.76	97.08
7	77	0.96	73.72
			Total = 6,104.95

The soils of the Little Wabash River watershed were formed by Illinoian glacial drift and windblown silt of the Wisconsinan age. The river valley is composed of relatively young alluvial matter from meltwaters of the Wisconsinan glacier. Three major soil associations occur in the watershed, including: Cowden-Cisne, Hosmer-Ava-Hickory, and Wakeland-Petrolia-Darwin.

METHODS

DESCRIPTION OF THE STUDY AREA-STREAM ORDER

Stream order here is based upon the Horton-Strahler classification (Horton 1945; Strahler 1954, 1957). In this system, ultimate unbranched tributary streams are defined as order 1 streams. Whenever two streams of equal order join, the resulting stream is designated as the next higher order. Thus, two order 1 streams join to make an order 2 stream, two order 2 streams make an order 3 stream, and so forth. Stream order is not affected by the confluence of a lower order stream. A stream link is defined as a reach of stream from its source to its first confluence with another stream or the reach of stream from one confluent stream to the next confluent stream. Data were derived from U. S. Geological Survey quadrangle maps with scales of 1:24,000 and 1:62,000. Morisawa (1957) determined that such maps are sufficiently accurate to depict virtually all order 1 streams.

In a fully bifurcate dendritic drainage net, each order 1 link joins with another to form an order 2 stream. Each order 2 link then joins with another to form an order 3 stream. This pattern continues until maximum stream order is reached, here equal to the characteristic, or integral portion of $1 + \log_2$ of the number of order 1 links. When the number of order 1 links is not an even power function of 2, the "extra" order 1 links appear as the mantissa of the base 2 logarithm. Big Creek would be an order 8 stream if the drainage net were of the fully bifurcate dendritic pattern. The stream would then have 141 order 1 links, 70 order 2 links, 35 order 3 links, 17 order 4 links, 8 order 5 links, 4 order 6 links, 2 order 7 links, and 1 order 8 link. It may be seen that Big Creek approaches this closely for orders 2 and 3. Big Creek differs more for order 1 links (high) and substantially for order 4 links (high). Hence, Big Creek is overdeveloped at the order 1 and, especially, order 4 levels. The stream never reaches the potential order 8 level. In fact, order 5, 6, 7, and 8 links are all absent.

Trellis drainage nets are characteristic of long, narrow valleys where numerous small streams flow down from the valley walls to join the principal stream following the thalweg of the valley. In an optimum trellis system, order 1 streams only flow into the principal stream. The confluence of the first two order 1 streams would produce an order 2 stream. All remaining influent order 1 streams would increase the number of order 2 links, but not the order of the principal stream.

FIELD SAMPLING

Benthic macroinvertebrate samples were collected in the Wabash River basin during autumn, 1976, and spring and summer, 1977. Qualitative samples from stations were taken using a combination of techniques including benthic buckets equipped with No. 30 mesh screen bottoms, fine-mesh aquatic D-frame nets, and hand picking. Ponar grab samples were taken from Wabash River sites and at other large-river sites plate samplers were exposed for

several weeks. All microhabitats present, including leaf packets, rocks, logs, and undercut banks were sampled for approximately 0.5 to 2 man-hours. All organisms, except molluscs, were preserved in Kahles fluid in the field. Molluscs were preserved in 95% ethanol. Sampling continued until the investigators believed that the sample was representative of a total assessment of the area and that further sampling would not add significant additional taxa. Similar habitats, if available, were examined both upstream and downstream of point sources. In addition, blacklight trap samples were taken from representative areas to assist in making immature and adult associations for later species identifications and subsequent reporting.

Field identifications were made to the lowest certain taxonomic level. Classification of identified organisms included assignment to one of four categories contained in a tolerance status list furnished by the Illinois Environmental Protection Agency (IEPA). These categories are summarized as:

intolerant - organisms whose life cycles are dependent upon a narrow range of ideal environmental conditions.

moderate - organisms lacking the extreme sensitivities to environmental stress of intolerant species, but unable to adapt to severe environmental degradation.

facultative - organisms able to survive over a wide range of environmental conditions and possessing a greater degree of tolerance to adverse conditions than either intolerant or moderate species. Some of the macroinvertebrates which utilize surface air for respiration are classified as facultative.

tolerant - organisms able to survive over a wide range of environmental extremes, including water of extremely poor quality.

Preliminary station classifications were assigned in the field to determine whether further upstream and/or downstream sampling was necessary to delineate zones of degradation. Station classifications followed the system developed by the IEPA as outlined below:

balanced environment - intolerant organisms numerically important in both number and diversity. For a station to be classified as balanced, intolerant organisms comprised more than 50% of the specimens collected at a site while moderate, facultative, and tolerant organisms comprised less than 50%.

unbalanced environment - intolerant organisms numerically less important than other forms combined, but combined with moderate forms, usually outnumber tolerant forms. For a station to be classified as unbalanced, organisms classified as moderate, facultative, and tolerant comprised more than 50% of the sample while intolerant organisms comprised more than 10% but less than 50% of the sample.

semi-polluted environment - intolerant organisms few or absent with moderate, facultative, and tolerant organisms predominating. For a station to be classified as semi-polluted, intolerant organisms comprised 10% or less of the organisms collected while moderate, facultative, and tolerant organisms combined comprised 90% or more of the sample.

polluted environment - generally only tolerant organisms present although some facultative forms may be observed. For a station to be classified as polluted either virtually all organisms collected were classified as tolerant or no organisms were present.

POINT SOURCES

Point sources in the Wabash River basin are summarized in Appendix 1. Map numbers (from Appendix 4), Illinois Natural History Survey (INHS) point source numbers, point source names, stream codes and IEPA point source map numbers, comments (if applicable), and upstream (A-1) and downstream (C-1) sampling sites (if appropriate) are included.

LOCATIONS OF SAMPLING SITES

Descriptions of the stream sites sampled in the Wabash River basin are contained in Appendix 2. Stream code and station number, location, date sampled, and stream classification assigned are included.

Legal descriptions were obtained from U. S. Geological Survey quadrangle maps with scales of either 1:24,000 or 1:62,500. Subdivisions of sections were made using a Geologist's Friend. When sections were not exactly one mile square, the section was divided into quarters of quarters of quarters based upon its actual size rather than by aligning the Geologist's Friend on the lower right corner of the section.

An apostrophe (') by the stream code and station number in both Appendix 2 and 3 indicates the results of plate samplers. This designation of plate samplers was not used on the maps in Appendix 4. Unless otherwise indicated, all samples were taken upstream of bridges. Distances from towns were calculated from the approximate "center" of the town as it appeared on the Department of Transportation, Office of Planning, Programming, and Environmental Science general highway maps for Illinois counties ($\frac{1}{2}$ inch to 1 mi series).

Sites where the stream was reduced to small, discontinuous pools or dry are included in Appendix 2.

INVENTORY TABLE

The benthic macroinvertebrate data from stream sampling stations are summarized in Appendix 3 as the highest taxonomic category which did

not alter the tolerance status, the number of organisms collected and/or estimated (*e. g.*, *Physa* or Chironomidae at some sites), total numbers observed for each tolerance status (intolerant, moderate, facultative, and tolerant), and the stream classification assigned. Tolerance status information was unavailable for several taxa. These were reported as unclassified in Appendix 3. An apostrophe (') by a station number indicates the result of plate samples.

MAPS

Appendix 4 contains maps of the Wabash River basin drawn using the Department of Transportation, Office of Planning, Programming, and Environmental Science general highway maps for Illinois counties ($\frac{1}{2}$ inch to 1 mi series) as base maps. Maps were checked for consistency and accuracy against the corresponding U. S. Geological Survey quadrangle 1:24,000 and 1:62,500 scale maps.

Segment boundary lines illustrated as a border of the maps in Appendix 4 were taken from IEPA maps illustrating point sources and water quality monitoring stations.

Symbols used on the prepared maps include:

solid circles - location of stream sample;

boxes - stream code, station number, and stream classification (balanced, B; unbalanced, UB; semi-polluted, SP; and polluted, P);

solid triangles - point sources;

open circles - point source number corresponding to INHS point source number (from Appendix 1).

STREAM CONDITIONS DETERMINED FROM BENTHIC MACROINVERTEBRATE SAMPLING

INTRODUCTION

The inventory table presenting the results of the benthic macroinvertebrate sampling at 882 stream sites in the Wabash River basin (Appendix 3) is summarized in Table 2 to illustrate the general distribution and relative abundance of organisms among the various stream systems. These data are further analyzed in Table 3 to describe the individual stream systems by the number of stations sampled, stream classifications, distributions of organisms among the four tolerance statuses, the predominant organisms, and the number and type of point sources sampled (wastewater treatment or industrial).

It is apparent from Tables 2 and 3 that the predominant stream classification was unbalanced with 48% of all stations sampled. The semi-polluted category ranked second in overall abundance, comprising 40% of all stations sampled. Balanced and polluted classifications each were 6% of the total number of stations sampled. Several sites were classified as dry even though some organisms were collected. These sites, comprising less than 1% of the total number of stations sampled, had all been dry prior to heavy rainstorms sometime within the 24-hour period prior to sampling. These stations were not classified.

Sampling in this watershed was conducted in late summer through early autumn, 1976 (upper Wabash River basin or B-prefix stations) and spring through summer, 1977 (Little Wabash River basin or C-prefix stations). Low water levels from the drought conditions of 1976 very likely contributed to the number of semi-polluted stations observed. As sampling progressed in the upper Wabash River basin, small order 1 streams were virtually all discontinuous or dry. In some areas this low water persisted downstream for considerable distances. Throughout the Wabash River valley in Illinois air temperatures were approximately 1 to 3 °F below normal for 1976 and precipitation ranged from approximately 5 inches below normal (Urbana, Champaign County) to 15 inches below normal (Albion, Edwards County) (Table 4).

The water regime for 1977 was more normal. While precipitation was slightly below normal during July at most reporting sites in the basin, it was normal to slightly above normal for August. Consequently, climatological conditions were more nearly normal during the sampling in the Little Wabash River basin than for the upper Wabash River basin.

This difference in water regime between the 1976 and 1977 sampling seasons had little apparent overall effect as far as stream classifications. While there may have been some slight differences in station classifications from unbalanced to semi-polluted, in general both the upper Wabash River drainage and the Little Wabash River basin were very similar in percent occurrence of the various station classifications. In both basins unbalanced and semi-polluted classifications occurred in approximately equal numbers within each basin and the percentages were virtually identical

Table 2. A summary of the composition and abundance of benthic macroinvertebrates and stream classifications by stream system in the Wabash River basin.

¹Summarized from annual summaries of climatological data for Illinois (U. S. Department of Commerce, National Oceanic and Atmospheric Administration, Environmental Data Service 1976, 1977). Air temperature expressed as mean annual, departure from normal in parentheses. Precipitation as total annual, departure from normal in parentheses. Normals for all stations are climatological standard normals based upon the period 1941 to 1970.

in both areas, 48% in the upper Wabash River and 47% in the Little Wabash River basins.

In fact, among the basins sampled by the Natural History Survey, the distribution (as percent) among the four stream classifications has been remarkably similar with most stations classified as unbalanced (46% to 54%), 38% to 48% as semi-polluted, 1% to 9% as balanced, and 1% to 6% as polluted. Although the exact percentages of the various stream classifications vary from watershed to watershed as a function of individual differences in basin lithography, time of year of sampling, or presence or absence of kinds of point sources or the types of agriculture practiced (pasture, intensive row crop, mixtures), the general breakdown among these classifications is so similar to suggest that Illinois streams share some broad, common characteristics or that the effects of agricultural non-point pollution are widespread and rather predictable.

An additional contributing factor to the number of semi-polluted sites observed was the overall infrequency of gravel and rock substrates with few rock riffles in many streams. Sites without eroding substrates or sites with gravel substrates which had been covered with a fine layer of silt or clay favored taxa which were assigned to either the moderate or facultative tolerance statuses such as small caenid mayflies, isopods, net-spinning caddisflies, and aquatic and semi-aquatic Heteroptera.

As only 10% of the organisms collected needed to be "intolerant" for a station to be classified as unbalanced, it is apparent that this would be a commonly observed classification, based upon the frequency of collection of amphipods, crayfish, intolerant mayflies, and other common intolerant taxa. In general, the stations classified as semi-polluted did not lack or, in many instances, even have lower numbers of such intolerant forms, but rather had extraordinary populations of moderate and facultative taxa including Coenagrionidae, Hydropsychidae, Isopoda, aquatic and semi-aquatic Heteroptera, aquatic Coleoptera, and caenid mayflies in addition.

Of nearly 100,000 individuals collected at the 882 sampling sites, only 14% of them belonged to taxa classified as intolerant, 18% as moderate, 28% as facultative, and 40% as tolerant. In overall abundance, Chironomidae predominated with approximately 20% of all organisms collected. Aquatic and semi-aquatic Heteroptera were second in overall abundance, comprising 16% of all organisms collected. Other important taxa in order of decreasing abundance were *Physa* 9%, aquatic Coleoptera 8%, Oligochaeta 7%, intolerant Ephemeroptera 6%, and Coenagrionidae 6%. These taxa comprised approximately 72% of all organisms collected.

The predominance of organisms among stream systems varied considerably especially among streams in the larger watersheds such as the Embarras, Vermilion, or Skillet Fork. Overall, however, Chironomidae were the predominant organisms at 15 of 40 stream systems, *Physa* at 5, aquatic and semi-aquatic Heteroptera at 9, aquatic Coleoptera at 5, Caenidae at 2, and Diptera (other), Hydropsychidae, and Oligochaeta each at 1 (Table 3).

The following discussion is organized by stream systems and summarizes briefly the stream classifications of 875 stations classified in the Wabash River basin. It is difficult, if not impossible, in many instances

to assign causes for the stream classifications observed. The stations designated as polluted were the easiest as the severe degradation of water quality and/or limited species diversity were often the direct result of a point source. Generally, immediately downstream from point sources and possibly for one or two stream miles further downstream, stream classifications would be semi-polluted. After flowing several miles further, conditions in these streams generally improved sufficiently to be classified as unbalanced. However, the extreme drought conditions experienced during 1976 reduced stream flows very likely to new minima. The overall effect upon stream classifications in the upper Wabash River basin (B-prefix stations) was probably to increase the number of semi-polluted sites observed as the intolerant forms burrowed deeper into the substrates, drifted downstream, or died, especially as low water levels observed at some stations caused many riffle areas to reduced drastically or to be dry. This was not such a severe problem in sampling the Little Wabash River basin during 1977 when the water regime was more average during sampling.

WABASH RIVER (B)

(Appendix 4, Maps 35, 36, 37, 52, 53, 54, 55, and 56)

Eight sites were sampled in the Wabash River. All of these were classified as semi-polluted. The distribution of organisms collected among the four tolerance status groups was heavily in favor of tolerant organisms, which comprised 84% of the individuals collected. In fact, Chironomidae comprised 54% of all individuals collected. Water levels were low in the river at the time of sampling, averaging approximately 10 inches deep, and all sites were virtually unshaded. Although the adjacent watershed was primarily agricultural with row crops of corn and soybeans on the flat land and pasture on the slopes, this would have little overall effect upon the water quality directly. In large rivers such as the Wabash, the adjacent watershed is less responsible for conditions at a particular point, except in the case of an untreated effluent flowing in at that point, than the entire watershed upstream of the point. In these large rivers most of the energy input is derived from upstream small order streams (orders 1, 2, and 3); very little in-stream production occurs by comparison. The river sediments in the main channel areas were composed chiefly of sand or mixtures of sand and gravel.

The six discharges entering the Wabash River directly apparently exerted little influence upon the stream classifications observed. Effluent from the wastewater treatment plants of Hutsonville, St. Francisville, Mt. Carmel, and Grayville and the industrial discharges of CIPS at Hutsonville and the Mt. Carmel Public Utility did not alter the stream classifications from semi-polluted. Since the Wabash River is an order 8 stream in this area, the effluents from these point sources would have to be of very poor quality to have more than a very localized influence upon stream quality.

FRENCH CREEK (BB)
(Appendix 4, Map 53)

Both sites sampled in French Creek were classified as semi-polluted. Water levels were extremely low at the time of sampling in August and throughout most of its length the stream was virtually unshaded. Substrate materials were chiefly sand and clay. The watershed of French Creek was primarily agricultural with row crops as the common land use. No point sources discharged into the basin.

Physa and *Coenagrionidae* were the predominant organisms collected, comprising 31% and 18%, respectively. Only 6% of the organisms collected were classified as intolerant. Such low frequencies are likely to be a result of lack of suitable microhabitats such as rock riffles.

BONPAS CREEK (BC)
(Appendix 4, Maps 51 through 54)

Among the nine sites sampled in the Bonpas Creek watershed, six were classified as unbalanced and three as semi-polluted. The watershed was primarily agricultural with corn and soybeans comprising most of the available acreage. In some areas, however, forest and pastures were observed next to the stream. In general, the stream was exposed fully to the sun; places where trees provided partial shading were uncommon to rare. Water level in the stream was extremely low, with at least 12 sites visited completely dry. Substrate materials at the various sampling stations were composed primarily of sand and clay, mixed with gravel or silt at several sites. Predominant taxa observed included Isopoda (24%) and aquatic and semi-aquatic Heteroptera (19%). Organisms classified as moderate were most abundant, followed by facultative taxa, intolerant, and tolerant ones.

The effects of the West Salem, North and South, wastewater treatment plants were minimal. Upstream of the outfall of each plant the stream was dry. Immediately downstream of each outfall, however, the receiving streams were classified as semi-polluted. These plants discharged into the headwaters of two streams and the effluents provided the available stream flow at the time of sampling.

COFFEE CREEK (BD)
(Appendix 4, Maps 52 and 54)

Only two sites, both classified as unbalanced, were sampled in Coffee Creek. The predominant taxa were species of aquatic and semi-aquatic Heteroptera, 23% of all organisms collected. Only 95 individuals were taken from both stations. However, this stream system was sampled following a recent flood which probably produced some benthic scouring. The adjacent watershed was heavily forested at one site in a conservation area; the second site was exposed to full sunlight with row crops predominating on its adjacent watershed. Substrate materials were chiefly clay, sand, and gravel. The lack of soft sediments deposited over the harder materials is likely the result of the recent high water levels.

EMBARRAS RIVER (BE)
(Appendix 4, Maps 15 through 33)

Two hundred four sites were sampled in the Embarras River system. Of these, 10% were classified as balanced, 52% as unbalanced, 31% as semi-polluted, and 7% as polluted. Of the nearly 30,000 organisms collected at these stations, 34% were classified as either intolerant or moderate, 31% as facultative, and 35% as tolerant. Overall, aquatic and semi-aquatic Heteroptera (21%) and Chironomidae (19%) were the predominant macroinvertebrates collected in the Embarras River system (Table 5).

The adjacent watershed varied widely among sampling stations. At most sites the stream was shaded to some degree by trees along the banks. Although urban influences affected several sites such as those near Mattoon or Charleston, the watershed was primarily agricultural, devoted to row crops and pasture. A few forested areas occurred.

Flow was very low at the time sampling took place, with the streams often appearing as stagnant or non-flowing. Substrates were primarily sand, mud, and gravel, often mixed with silt, debris, and clay.

Of 52 point sources located in the Embarras River basin, (42 wastewater treatment plants and 10 industrial sources), 13 were not discharging at the time of sampling. Some categorized as industrial may also have included some non-industrial components. Results of sampling these discharges may be categorized into major groups by stream conditions either upstream or downstream as point sources where: (1) downstream sites were an improvement over upstream stream classifications; (2) the downstream site was degraded when compared to the upstream stream classification; (3) both the upstream and downstream sites had the same stream classification; or (4) either the upstream or downstream site was dry.

At the Tolono wastewater treatment plant and the Alvis Standard Service Station stream conditions actually were improved downstream of the point source discharges. In both instances, streams were classified as polluted upstream of the outfalls, classified as semi-polluted immediately downstream of the Tolono plant and unbalanced downstream of the Alvis station.

The wastewater treatment plant outfalls of Savoy and Tuscola-North exerted minimal or short-term effects upon their respective receiving streams. Although the Savoy plant sites were classified as unbalanced immediately upstream and semi-polluted downstream in the unnamed tributary, stream conditions in the Embarras River improved within four miles downstream. The Savoy plant discharges into the headwaters of the Embarras River where its effect could be greater than in downstream reaches where more flow was available for dilution. In Tuscola-North conditions changed from unbalanced to polluted in Hayes Branch, but within two miles downstream improved to be classified as unbalanced.

The General Electric discharge in Mattoon did have a degrading effect upon Kickapoo Creek. Stream classification changed from unbalanced immediately upstream of the outfall to semi-polluted after discharge of

Table 5. A summary by stream system of the number of stations sampled, station classifications, distributions of organisms among the four tolerance statuses, predominant organisms, and number and type of point sources sampled in the Embarras River basin.

¹Many of the point sources listed did not discharge to a receiving stream. Details for each point source are contained in Appendix 1. WT = wastewater treatment discharge. IND = industrial discharge.

²Figures for stream classifications calculated from column totals; % of total organisms and predominant organisms calculated from column and line totals presented in Table 2 and Appendix 3.

the effluent. Conditions continued to degrade as Kickapoo Creek flowed through Mattoon, with the stream classified as polluted.

Point sources for which both the upstream and downstream sites had the same classification included the wastewater treatment plants of Newton, Bridgeport, Lawrenceville, Flat Rock, Martinsville, Charleston, Mattoon, Tuscola-South, and Greenup; the Red Hills State Park South, Texaco, Inc. 001 + 002, Martinsville District C-3 OR, and the Lawrenceville-Vincennes Airport. Almost all of these sites were classified as unbalanced both upstream and downstream. The Greenup and Mattoon wastewater treatment plant sites were classified as polluted both upstream and downstream of each outfall while the Tuscola-South and Bridgeport plant sampling sites were classified as semi-polluted. The Greenup effluent flows into a small tributary of the Embarras River and flows into the Embarras River within one stream mile. The effect upon the Embarras River is minimal as water quality remains good in that portion of the river (classified as unbalanced). The Martinsville wastewater treatment plant sampling stations were the only ones to be classified as balanced both upstream and downstream of the outfall, the result of an unusual number of amphipods collected.

There were 13 sites where the stream immediately upstream of the discharge was dry. Effluent quality was low at the Sumner, Casey, Toledo, and Villa Grove wastewater treatment plants, the Newton lagoon, and the Cumberland elementary and high schools, and the receiving streams were classified as polluted downstream of these discharges. The effluents of the Oblong and Arcola wastewater treatment plants, the University of Illinois Willard Airport, Francis Mobile Home Park, and Tuscola-South wastewater treatment plant were of somewhat better quality as stream classifications were semi-polluted downstream of their discharges. Downstream of Anaconda Brass in Mattoon and the Martinsville District C-3 SO the receiving streams were classified as unbalanced. In general, however, quality improved by the time the receiving stream had flowed a few miles farther downstream with stream classifications generally becoming unbalanced.

The Embarras River system was the largest Wabash River tributary sampled in this inventory. The 204 sites sampled were distributed among 19 smaller stream systems, unnamed tributaries, and the Embarras River itself with 32 stations sampled. Most of these Embarras River tributaries, as summarized in Table 5, were small, represented by 10 or fewer stations. Only five tributaries were large enough to have more than 10 sampling sites: North Fork (45 stations), small direct tributaries (23), Scattering Fork (18), Kickapoo Creek (13), and Brushy Fork (11).

Most stations were classified as either unbalanced (105) or semi-polluted (64), with rather even distributions in most stream systems. Notable exceptions were observed in the Embarras River where 81% of the stations sampled (26) were either balanced or unbalanced sites; in the North Fork watershed where 91% (41) were either classified as balanced or unbalanced; and the Scattering Fork where 89% (16) of the stations sampled were either semi-polluted or polluted.

A variety of taxa predominated in various stream systems, representing all the tolerance statuses. Chironomidae were among the predominant taxa

observed at 14 of the 21 streams or stream systems summarized in Table 5. Aquatic and semi-aquatic Heteroptera ranked second in number of occurrences with 8; Sphaeriidae, 4; Decapoda, Oligochaeta, and other Diptera, each 3; intolerant Ephemeroptera, *Physa*, and Amphipoda, each 2; and Tricladida and Isopoda, each 1.

SUGAR CREEK (BF)
(Appendix 4, Map 37)

Twenty-six sites were sampled in the Sugar Creek system. Of these 12% were classified as balanced, 46% as unbalanced, 27% as semi-polluted, and 15% as polluted. Tolerant organisms predominated, comprising 58% of the total number of individuals collected. In fact, Chironomidae comprised 33% of the total number of organisms collected. Miscellaneous Diptera, crayfish, and isopods were also abundant in the watershed.

The basin was primarily agricultural with row crops and pasture common. Natural wooded areas, as well as low shrubbery along the banks, were frequently observed along the streams. At virtually all sites sampled, the stream was heavily shaded. At the time of sampling water levels were very low and some oil was detected at the surface of the water and the surrounding areas at several sites. Principal substrate materials included sand, sand and gravel mixtures, or mud and debris.

Of seven point sources located in the Sugar Creek watershed, four were wastewater treatment plants and three were industrial point sources. The Palestine wastewater treatment plant and Briggs Manufacturing Company both exerted minimal effects upon Sugar Creek. Both upstream and downstream sampling sites near these point sources were classified as unbalanced. In Robinson both the wastewater treatment plant and Robinson Industries lagoon discharges exerted an influence upon stream quality. Upstream from the outfalls the stream was classified as unbalanced while downstream the stream classification was polluted. Below the lagoon outfall the stream classification did not improve until approximately four miles further downstream. Below the wastewater treatment plant outfall, however, stream recovery occurred within one-quarter mile and the site was classified as balanced due to the unusually large number of crayfish collected. Both upstream and downstream sites of the Marathon Oil Company were classified as polluted. There was no discharge from the Lincoln Trail College into Sugar Creek, presumably only because school was not in session at the time of sampling. Crawford County Country Club's discharge was to a lake.

RACCOON CREEK (BG)
(Appendix 4, Map 36)

Six sites were sampled in the Raccoon Creek watershed. Of these, one station was classified as balanced, three as unbalanced, and two as semi-polluted. Aquatic and semi-aquatic Heteroptera (28%) and Chironomidae (25%) predominated. The watershed adjacent to the various sampling sites varied with combinations of forest, open meadows, pasture, and row crops occurring. Likewise, stream shading varied, ranging from virtually unshaded to totally shaded. Stream substrate materials were primarily sand, occasionally mixed

with gravel. No discharging point sources occurred in the watershed.

MILL CREEK (BH)
(Appendix 4, Map 35)

Twenty-eight sites were sampled in the Mill Creek system. Of these, 11% were classified as balanced, 75% as unbalanced, 11% as semi-polluted, and 3% as polluted. The most abundant organisms collected were classified as tolerant (63% of all individuals collected), the least abundant as moderate (only 4% of all individuals collected). Overall, Chironomidae (29%) and other Diptera (19%) were the predominant macroinvertebrates collected in the watershed.

The watershed was primarily agricultural with corn as the principal row crop on the flat lands and pasture predominating on the steeper slopes. Some sites were wooded, partially shading the stream. Substrates were chiefly sand often mixed with either mud or gravel.

The Marshall wastewater treatment plant discharged into Mill Creek. Its effect upon the receiving stream was minimal and short-term. Stream conditions degraded to polluted downstream of the outfall from semi-polluted upstream of the discharge. However, by the time the stream had flowed approximately one mile downstream conditions had improved sufficiently to be classified as unbalanced.

SUGAR CREEK (BI)
(Appendix 4, Map 35)

Only two stations were sampled in the Sugar Creek watershed, one classified as unbalanced, the other as semi-polluted. The watershed was primarily agricultural although some low trees and shrubs and several small woodlots occurred along the adjacent watershed. The creek was partially shaded at both sites sampled. Predominant substrate materials were sand and mud. Facultative organisms comprised 62% of the organisms collected at these stations with aquatic and semi-aquatic Heteroptera predominating, 58% of all individuals collected. There were no discharging point sources in this watershed.

BIG CREEK (BJ)
(Appendix 4, Maps 34 and 35)

Of 24 sites sampled in the Big Creek basin, 17% were classified as balanced, 58% as unbalanced, 17% as semi-polluted, and 8% as polluted. Chironomidae comprised 49% of all organisms collected in the watershed and together with *Physa* and aquatic and semi-aquatic Heteroptera accounted for 71% of the nearly 2,700 individuals collected. Agricultural interests predominated in this basin although urban influences were important at several sites. One site was in the process of being dredged. In general, the stream itself was shaded or semi-shaded by trees. Substrate materials were chiefly sand mixed with either gravel or rock.

Two discharging point sources were located in the basin. The Marathon Station discharge actually improved stream conditions with the small unnamed tributary being classified as unbalanced downstream. The Marshall-East wastewater treatment plant effluent did not alter stream classifications, both immediately upstream and downstream of the outfall the stream was classified as polluted. This plant, however, is located in the headwaters of Little Creek. In a small headwater stream the impact of an effluent would be greater since the dilution ratio would be low. By the time the stream had flowed approximately two miles farther downstream conditions had improved enough for Little Creek to be classified as unbalanced.

ASHMORE CREEK (BK)
(Appendix 4, Map 35)

Two sites were sampled in Ashmore Creek. One was classified as unbalanced, the other as semi-polluted. *Physa* and Chironomidae were the predominant organisms collected, comprising 43% and 39%, respectively. Forest was the primary vegetation of the adjacent watershed, but the primary activity in the watershed was farming. On agricultural land row crops, especially corn, were important. The substrate materials observed were combinations of either sand and mud or sand and gravel. No point source discharged into Ashmore Creek.

CLEAR CREEK (BL)
(Appendix 4, Map 14)

Among the eight stations sampled in the Clear Creek basin, two were classified as balanced and six as unbalanced. Although much of the watershed was forested, fields and pastures were frequently observed adjacent to the stream. Only one site was exposed to direct sunlight; the others were heavily shaded. Substrates were composed of sand and gravel. At the time of sampling the water levels were very low and blue-green algae was plentiful at most sites. Chironomidae were the predominant benthic macroinvertebrates collected, comprising 17% of all individuals taken. However, intolerant organisms comprised 37% of all organisms collected, the most abundant, with tolerant organisms next in abundance with 33% of the total, facultative organisms with 23%, and finally, moderate organisms as the least abundant with only 7% of the individuals collected. No point sources discharged into Clear Creek.

SUGAR CREEK (BM)
(Appendix 4, Maps 13 and 14)

Twelve sites were sampled in Sugar Creek. Of these, four were classified as unbalanced and eight as semi-polluted. The surrounding watershed was forested and one site was located on the Paris golf course. The predominant stream substrates were sand either mixed with gravel, silt, mud, and/or debris. Chironomidae were by far the most abundant organisms collected, comprising 54% of all organisms collected.

Two wastewater treatment plant discharges were investigated. These

two effluents had little long-term effect upon stream conditions. Both the Paris-North wastewater treatment plant and the Sycamore Hills Country Club sites were classified as semi-polluted upstream of their respective outfalls. The stream classification at the Sycamore Hills Country Club remained semi-polluted downstream of its outfall and the flow contributed by the Paris-North treatment plant actually improved stream conditions sufficiently to be classified as unbalanced. The Paris-South wastewater treatment plant effluent changed stream classifications from unbalanced upstream to semi-polluted downstream. The two Paris wastewater discharges are in close proximity and discharge to the same receiving stream. The stream flows only a short distance before the second discharge enters; thus, there is little flow time for a "recovery" zone for the North plant.

BROUILLETTS CREEK (BN)
(Appendix 4, Maps 12 and 13)

Among the 15 sites sampled in Brouilletts Creek, 10 stations were classified as unbalanced and five as semi-polluted. Chironomidae (23%) and Coenagrionidae (14%) predominated at these stations. Approximately 1,700 individuals were collected at these sites and there was a reasonably even distribution of organisms among the four tolerance status groups. Substrate materials at various stations were primarily sand in combination with mud, gravel, or debris. The adjacent watershed included combinations of forest, pasture, and row crops such as corn and soybeans.

There was only one point source discharging into Brouilletts Creek, the Chrisman wastewater treatment plant. Its effect upon the stream was minimal. Both the upstream and downstream sampling stations were classified as semi-polluted and stream conditions improved farther downstream about one mile to be classified as unbalanced.

LITTLE VERMILION RIVER (BO)
(Appendix 4, Map 12)

Of 14 sites sampled in the Little Vermilion River system, 43% were classified as unbalanced, 36% as semi-polluted, and 21% as polluted. Principal organisms collected included aquatic Coleoptera (18%) and Chironomidae (18%). Of approximately 1,000 individuals collected, in general one third was tolerant organisms, one third facultative, and one third a combination of intolerant and moderate. The stream substrates were primarily gravel, mud, and sand. Woods and pasture were the predominant land uses in the adjacent watershed.

The two discharging point sources into the Little Vermilion River exerted minimal effect upon the stream. The site upstream of the Georgetown wastewater treatment plant was classified as unbalanced with conditions degrading to polluted immediately downstream. However, conditions improved within 0.5 mile flow downstream to be classified as unbalanced. The Ridge Farm wastewater treatment plant effluent reduced stream conditions to the polluted classification immediately downstream of its outfall. The recovery was rapid with conditions improving to unbalanced by the time the stream had flowed approximately 1.5 miles farther downstream.

VERMILION RIVER (BP)

(Appendix 4, Maps 3 through 8, 10, 33, 35, 36, 37, 38, 52 through 56)

One hundred fifty-three sites were sampled in the Vermilion River basin. Of these, 6% were classified as balanced, 35% as unbalanced, 51% as semi-polluted, and 8% as polluted. Of nearly 20,000 individuals collected at these stations, approximately 15% were classified as intolerant, 28% as moderate, 26% as semi-polluted, and 31% as tolerant. Chironomidae and aquatic Heteroptera were the predominant taxa, comprising 14% and 16% of the total organisms collected. This varied significantly among the various tributary streams, however, with *Ferrissia*, Tricladida, intolerant mayflies, and miscellaneous Diptera predominating at certain sites. The adjacent watershed was primarily agricultural, devoted to row crops and pasture, with occasional patches of forest or woodlots. Some urban influences such as Champaign-Urbana and Rantoul or Danville exerted strong effects which were noticeable for considerable distances downstream. In general, the stream substrates were primarily sand in combination with mud, gravel, or silt, especially in the tributaries. At the time of sampling the flow in most sites was very low to stagnant.

The Vermilion River basin was the second largest Wabash River tributary sampled in this inventory. The 153 sampling sites were distributed among six smaller stream systems and the Vermilion River itself with three sites sampled. These are summarized in Table 6. Since the Salt Fork and Middle Fork tributaries were still rather large, a further breakdown was provided in Table 6 for these two major Vermilion River tributaries.

Most stations were classified as either unbalanced (54) or semi-polluted (78). The Salt Fork system was the only Vermilion River tributary in which the number of semi-polluted and polluted stations considerably outnumbered the balanced-unbalanced ones. Sixty percent (41) of the sites were classified as semi-polluted. Two factors contributed to these observations. Sampling in the Salt Fork was conducted during late summer and autumn, 1976, a severe drought period. The ditched and channelized portions, a result of the drainage of the Champaign County marshes, in the Salt Fork system contain most stream miles, thereby favoring soft, depositing substrates in the intensively farmed watershed. In addition, the large urban influences of Rantoul and Champaign-Urbana affect the Upper Salt Fork Drainage Ditch and the Saline Ditch and Salt Fork, respectively. These factors combined to produce stream conditions which were of poorer overall quality.

A variety of taxa predominated in the various tributary systems, representing all the tolerance statuses. Among the major tributaries, no one taxon predominated. Chironomidae were important at four, aquatic and semi-aquatic Heteroptera at three and intolerant Ephemeroptera and Tricladida at two each, and *Ferrissia*, Coenagrionidae, other Diptera, *Physa*, and Oligochaeta each at one.

Thirty point sources actually discharged into the Vermilion River watershed. At 12 of these the stream classification was unchanged from upstream to downstream of the outfall. Those sites classified as semi-polluted both upstream and downstream of point source discharges included General Electric in Danville, the Country Manor and Twin Orchard Mobile

Table 6. A summary by stream system of the number of stations sampled, station classifications, distributions of organisms among the four tolerance statuses, predominant organisms, and number and type of point sources sampled in the Vermilion River basin.

¹Many of the point sources listed did not discharge to a receiving stream. Details for each point source are contained in Appendix 1. WT = wastewater treatment discharge. IND = industrial discharge.

²Figures for stream classifications calculated from column totals; % of total organisms and predominant organisms calculated from column and line totals presented in Table 2 and Appendix 3.

Home Parks, and the wastewater treatment plants of Westville, Rantoul, and St. Joseph. At the Lebanon Chemical Company (Agrico Chemical Company), the Chanute Test Cell Dome and the Chanute wastewater treatment plant, the stream classifications were polluted both upstream and downstream of these point sources. Unbalanced conditions both upstream and downstream were observed at the Oakwood Boy Scouts of America Camp Drake and the Illinois Power Company at Newton. Only the Oakwood wastewater treatment plant had balanced conditions both upstream and downstream of the discharge.

At three stream sites conditions actually improved downstream of the point source discharges. At both the Illinois Central Gulf railroad and Shady Acres Mobile Home Park, the receiving streams were classified as polluted upstream of the outfalls, but classified as semi-polluted downstream. At the Potomac Community Unit 10 school, stream conditions changed from unbalanced upstream to balanced downstream, due primarily to the large number of intolerant mayflies collected.

At six sites including the wastewater treatment plants of Danville, Hoopeston, Catlin, Champaign-Urbana, and General Motors and Lauhoff Grain industrial discharges, the downstream sampling site was classified as being of poorer quality than the upstream site. At Catlin, Hoopeston, and Lauhoff Grain the effluent exerted minimal effects as stream classifications returned to those as upstream within one stream mile downstream flow.

At several sites the upstream stations were dry and the downstream station was classified as unbalanced. This occurred downstream from Newton School, West Cove Christian High School, and the Rossville Packing Company. At the Bohn Al and Brass Corporation the downstream site was semi-polluted and at the Skelly Oil Station and Vistron-Sohigro-Potomac it was dry. Only the wastewater treatment plant of Paxton had a polluted site downstream of its discharge, but stream conditions had improved sufficiently to be classified as unbalanced by the time the stream had flowed one mile.

Two point sources, the Sidney Elementary school and the Votec Nursing Home, were not discharging at the time of sampling.

UNNAMED TRIBUTARIES OF WABASH RIVER (BZ) (Appendix 4, Maps 33, 35 through 38, 52 through 56)

Among the six stations sampled in unnamed tributaries of the Wabash River were one site classified as balanced, two sites as unbalanced, and three sites as semi-polluted. The watersheds were primarily agricultural with row crops, pasture, and open meadows comprising most of the available acreage. The stream banks were commonly lined with trees, virtually shading all of the sites sampled. Substrate materials were primarily silt, clay, and gravel. The predominant taxa observed at these sites included miscellaneous Diptera (23%), aquatic and semi-aquatic Heteroptera (16%), and Hydropsychidae (15%). There was no discharging point source into any of these unnamed tributaries of the Wabash River.

SMALL NAMED TRIBUTARIES OF WABASH RIVER (BZ_)
(Appendix 4, Maps 52, 54, 55, and 56)

Twenty-five sites were sampled in small named tributaries of the Wabash River. Of these, 4% were classified as balanced, 64% as unbalanced, and 32% as semi-polluted. Stream substrates were extremely variable with sand, mud, and gravel, or combinations of mud, clay, sand, or silt. Overall, among approximately 1,800 organisms collected, Chironomidae and aquatic and semi-aquatic Heteroptera were the most abundant organisms, comprising 18% and 15%, respectively. Tolerant organisms comprised 40% of all individuals collected.

The watersheds of these small streams were primarily in pasture and row crops although several wooded sites and one swampy site were observed. Stream shading ranged from virtually unshaded to totally shaded.

No point source discharged into any of these small named tributaries.

LITTLE WABASH RIVER (C)
(Appendix 4, Maps 39, 40, 41, 43, 44, 48, 49, 50, and 56)

Of 23 sites sampled in the Little Wabash River, 16 were classified as unbalanced, eight as semi-polluted, and one as balanced. There was a reasonably even distribution of organisms collected among the four tolerance statuses with facultative organisms as the most abundant, tolerant organisms the least. Overall, Hydropsychidae (16%), aquatic and semi-aquatic Heteroptera (13%), and Chironomidae (13%) were the predominant benthic organisms collected in the Little Wabash River.

The watershed was primarily agricultural with forest or woodlots occupying the slopes. Although row crops were common, pastures and some hog lots were evident. Substrate materials in the streams included mud, sand, and gravel, occasionally with silt or debris. Water levels were extremely low during the time sampling occurred. Shading by riparian vegetation ranged from full exposure to sunlight to partially and totally shaded.

The Louisville and Carmi wastewater treatment plants discharge into the Little Wabash River. These treated effluents did not exert a major influence upon the quality of the receiving stream. At the Louisville plant upstream from its outfall, the river was classified as unbalanced. Upstream from the Carmi outfall, the Little Wabash River was classified as semi-polluted. The observed stream classifications did not change after the discharge entered the stream.

SKILLET FORK (CA)
(Appendix 4, Maps 57 through 61, 64)

One hundred sixteen sites were sampled in the Skillet Fork basin. Of these, 6% were classified as balanced, 51% as unbalanced, 42% as semi-polluted, and 1% as polluted. Of approximately 8,000 organisms collected,

aquatic and semi-aquatic Heteroptera predominated, 19% of the individuals taken. The distribution of organisms among the four tolerance status groups was in favor of the facultative (39%) and tolerant (31%) groups.

Much of the adjacent watershed was agricultural with row crops and pasture predominating and occasional forest or woodlots evident. Stream substrates were a combination of sand, mud, and/or gravel. Flow was very low at the time of sampling, often appearing as stagnant or non-flowing. The stream shading by riparian vegetation ranged from full exposure to the sun to complete shading. Although 19 point sources were located in the Skillet Fork basin, none were discharging at the time of sampling.

The Skillet Fork basin was the third largest Wabash River tributary sampled in this inventory. The 116 sites were distributed among the Skillet Fork itself, small direct tributaries, and 22 tributaries. With the exception of Main Outlet Ditch (22 stations) and Horse Creek (14 stations), no other tributary had more than 11 sampling stations. Most, in fact, contained only one, two, or three sampling sites. Table 7 includes summary data for the Skillet Fork basin.

All tolerance status groups were represented among the predominant taxa in the various tributary systems, including aquatic and semi-aquatic Heteroptera (14), Chironomidae (7), Caenidae and *Physa* (6 each); Coenagrionidae, Coleoptera, Amphipoda, snails (non-*Physa*), other Diptera, Isopoda, and Oligochaeta (5 or less).

BIG CREEK (CB) (Appendix 4, Maps 48 and 49)

The six sites sampled in Big Creek were classified as semi-polluted. Aquatic Coleoptera were the predominant organisms collected, comprising 30% of all individuals taken. In addition Coenagrionidae and *Physa* were numerically important. The adjacent watershed was a combination of woodlots and forest, fields, and pasture. At the time of sampling the water level in the creek was very low and at most sites the creek was exposed to direct sunlight. The substrate was composed chiefly of sand and clay with some gravel.

The only discharging point source at the time of sampling was the Albion wastewater treatment plant. The effect of the effluent upon the stream cannot be accurately determined since the stream was dry upstream from the outfall. Two sites sampled downstream of the plant outfall, however, were classified as semi-polluted.

POND CREEK (CC) (Appendix 4, Maps 47 and 49)

Among seven stations sampled in the Pond Creek system, 29% were classified as unbalanced, 42% as semi-polluted, and 29% as polluted. Aquatic Oligochaeta were the predominant organisms observed, comprising 73% of the nearly 1,700 individuals collected. *Physa* were also numerically

Table 7. A summary by stream system of the number of stations sampled, station classifications, distributions of organisms among the four tolerance statuses, predominant organisms, and number and type of point sources sampled in the Skillet Fork basin.

¹Many of the point sources listed did not discharge to a receiving stream. Details for each point source are contained in Appendix 1. WT = wastewater treatment discharge.

²Figures for stream classifications calculated from column totals; % of total organisms and predominant organisms calculated from column and line totals presented in Table 2 and Appendix 3.

important so that tolerant organisms comprised 87% of all individuals collected in the watershed.

The watershed was primarily agricultural with row crops and some pasture. However, there was some urban influence and oil fields were evident as well. Trees along the stream banks provided some slight shade, but most sites sampled were virtually unshaded. In addition, water levels were very low at the time of sampling.

Only the wastewater treatment plant of Fairfield discharged into the Pond Creek basin. The effect of the Fairfield discharge persisted downstream in Johnson Creek to its confluence with Pond Creek, approximately two miles from the outfall. There was no discharge from the Jasper Community Consolidated school at the time of sampling.

ELM RIVER (CD) (Appendix 4, Maps 43, 44, 46, 47, and 48)

Thirty-four sites were sampled in the Elm River system. Of these, 44% were classified as unbalanced, 53% as semi-polluted, and 3% as polluted. Over one-half of the 3,600 individuals collected were tolerant organisms with Chironomidae comprising 33% of the total. *Physa* were also numerically important.

Land use was primarily agricultural, devoted to some pasture and forest as well as row crops. One oil well was observed. Stream substrates were essentially mixtures of sand, mud, and clay. Water levels were very low at the time of sampling and the stream was generally unshaded by riparian vegetation.

Three of the six point sources in the Elm River watershed discharge several times per year; thus there was no effluent at the time of sampling. The other three, the wastewater treatment plants of Flora and Cisne, and the Charlie Brown Memorial Park exerted short-term effects upon the receiving streams. At Flora, the stream degraded from semi-polluted to polluted, at Cisne from unbalanced to semi-polluted, after the effluent entered the receiving stream. In both cases, however, stream conditions improved to the upstream classification within less than five stream miles of flow downstream. The upstream and downstream sampling sites of the Charlie Brown Memorial Park were both classified as unbalanced.

VILLAGE CREEK (CE) (Appendix 4, Map 48)

The four sites sampled in Village Creek were classified as semi-polluted. Aquatic Coleoptera and aquatic and semi-aquatic Heteroptera were the predominant organisms, comprising 31% and 18%, respectively, of the total number of individuals taken. The adjacent watershed was a combination of forest, pasture, and row crops. Predominant substrate types included mud and gravel. At the time of sampling the stream was apparently non-flowing and only partially shaded by riparian vegetation. There were no point sources discharging into Village Creek.

CLEAR POND CREEK (CF)
(Appendix 4, Map 48)

Of five stations sampled in Clear Pond Creek, one was classified as unbalanced and four as semi-polluted. Aquatic and semi-aquatic Heteroptera (22%) and aquatic Coleoptera (21%) were the predominant organisms collected. All sites were surrounded by agricultural land, primarily row crops and pasture. One marshy area was observed and an oil well also. Substrate materials were chiefly mud, clay, and gravel. The stream was non-flowing at the time of sampling and shaded approximately 50% to 75% by riparian vegetation. No point sources discharged into Clear Pond Creek.

SUGAR CREEK (CG)
(Appendix 4, Map 48)

The ten stations sampled in the Sugar Creek watershed were evenly divided between the unbalanced and semi-polluted classifications. At the sites stream shading ranged from virtually unshaded to totally shaded. The watershed was entirely in row crops with several woodlots observed. Stream flow was low, often appearing as stagnant. Substrates were primarily sand, mud, gravel, and silt. Predominant taxa were aquatic Coleoptera (25%) and aquatic and semi-aquatic Heteroptera (15%).

The Parkersburg School did not discharge into Sugar Creek at the time of sampling and the Calhoun Elementary School discharged into a sand filter.

FOX RIVER (CH)
(Appendix 4, Maps 42, 45, and 48)

Eighteen sites were sampled in the Fox River system. Of these, 50% were classified as unbalanced, 39% as semi-polluted, and 11% as polluted. The distribution of organisms among the four tolerance statuses was not even as 81% of the approximately 1,200 individuals collected were tolerant or facultative organisms. Moderate organisms were the least abundant, comprising only 8% of the individuals collected. Overall, Chironomidae (24%) and Oligochaeta (16%) were the predominant organisms.

The Olney wastewater treatment plant was the only effluent that exerted an effect upon its receiving stream, an unnamed tributary of the Fox River. Stream classification changed from semi-polluted upstream of the outfall to polluted immediately downstream. The Kincaide Mobile Home Park had no effect upon the receiving stream as both the upstream and downstream sampling sites were classified as unbalanced. Although the stream was classified as polluted downstream of the AMF Chrome Waste Wheelgoods outfall, conditions improved sufficiently by the time the stream had flowed two miles farther downstream to be classified as unbalanced. The Olney Homes, Inc. discharged to a lagoon and the Dundas Elementary School was not discharging at the time of sampling.

Land use adjacent to sampling sites varied widely. Although primarily agricultural and devoted to row crops, some pastures and small woodlots were apparent. The streams were generally at least 50% shaded by riparian

vegetation at most sampling sites. Substrate materials were chiefly mud, clay, and sand or gravel.

HOG RUN CREEK (CI)
(Appendix 4, Map 45)

This stream was essentially dry at the time of sampling. There was some flow which was the result of a thunderstorm within the previous 24-hour period. Consequently, only 17 organisms, primarily aquatic and semi-aquatic Heteroptera were collected.

BIG MUDDY CREEK (CJ)
(Appendix 4, Maps 42 and 44)

Of the 24 sites sampled in the Muddy Creek watershed, 62% were classified as unbalanced, 38% as semi-polluted. *Physa* and Chironomidae were the predominant organisms collected, comprising 18% and 17%, respectively. The adjacent watershed included forest, pasture, and row crops. Substrate materials included clay, mud, and sand. Extremely low flow conditions existed at all sampling sites in the watershed.

PANTHER CREEK (CK)
(Appendix 4, Maps 43 and 44)

The single site sampled in Panther Creek was classified as unbalanced. The site was surrounded by pasture and the stream was lightly shaded by riparian vegetation. The substrate was a mixture of mud, clay, and debris. There was apparently no flow at the time of sampling. The predominant organisms included Caenidae (33%) and Amphipoda (28%). No point source was discharging into Panther Creek.

DISMAL CREEK (CM)
(Appendix 4, Maps 41 and 43)

The three sites sampled in Dismal Creek were classified as unbalanced. The watershed was entirely agricultural with row crops predominating. Sand and mud were the chief substrate materials present. Facultative organisms were the most abundant, moderate the least. Overall, Chironomidae and Caenidae were the predominant macroinvertebrates collected in Dismal Creek, comprising 23% and 21%, respectively, of all organisms collected. No discharging point source was observed.

LUCAS CREEK (CN)
(Appendix 4, Maps 41 through 43)

Two stations were sampled, one classified as unbalanced and the other as semi-polluted. Chironomidae (28%) and Caenidae (20%) were the predominant organisms collected at these sites. The stream had probably

been dry the previous day with the flow observed the result of a brief thunderstorm during the previous 24-hour period. The adjacent watershed was primarily agricultural. Bottom materials were a combination of sand, gravel, and vegetative debris. There was no point source discharging into Lucas Creek.

BISHOP CREEK (CO)
(Appendix 4, Maps 41 and 42)

Six stations, classified as semi-polluted, were sampled in Bishop Creek. Facultative and tolerant organisms comprised 81% of the organisms collected with Chironomidae (30%) and Caenidae (18%) as the predominant taxa observed.

Water levels were very low in Bishop Creek at the time of sampling. In many instances the water appeared stagnant. Low flow in combination with rather uniform substrates of sand and mud very likely contributed substantially to the semi-polluted classifications observed. No discharging point sources were located in the Bishop Creek watershed. Row crops and pasture were the primary land uses on the adjacent watershed.

SALT CREEK (CP)
(Appendix 4, Maps 40, 41, and 42)

Of 14 sites sampled in the Salt Creek watershed, 29% were classified as unbalanced, 57% as semi-polluted, and 14% as polluted. Chironomidae were the predominant organisms collected, comprising 50% of all individuals taken. *Physa* were also numerically important so that tolerant organisms comprised nearly 75% of all individuals collected. Substrate materials were chiefly sand, mud, and, occasionally, gravel. Stream flow was very low, often appearing stagnant, at the time of sampling. The adjacent watershed was primarily agricultural, including row crops, pasture, and occasional woodlots or forest.

Four wastewater discharges were located in the Salt Creek watershed. The Teutopolis wastewater treatment plant and the Lincoln Lodge Motel both had upstream sites which were classified as unbalanced. Immediately downstream of their discharges, stream classifications were semi-polluted. In both instances, however, stream conditions improved to be classified as unbalanced within two miles flow downstream. The station upstream of the Effingham wastewater treatment plant outfall in an unnamed tributary was classified as polluted. The receiving stream was also classified as polluted downstream of its outfall. The effect of the Effingham effluent persisted in Salt Creek for at least six miles downstream. Conditions improved to be classified as unbalanced, with a decline in the total number of tolerant species. The diversity of the upstream areas above the outfall did not occur. The Watson wastewater discharged into an unnamed tributary of Salt Creek. Although no samples could be taken at the plant, the stream was classified as semi-polluted two miles downstream of the outfall. This effluent exerted a minimal effect upon water quality in Salt Creek, however, since the Salt Creek sampling sites at the mouth of the unnamed tributary and downstream nearly 10 miles were classified as unbalanced. Martin Country Meats discharged to evaporation lagoons without outlets.

FULFER CREEK (CQ)
(Appendix 4, Map 41)

Three sites were sampled in Fulfer Creek. Of these, one was classified as unbalanced, two as semi-polluted. Caenidae and aquatic and semi-aquatic Heteroptera were the predominant organisms collected, comprising 21% and 19%, respectively, of the individuals taken. The adjacent watershed of Fulfer Creek sites included row crops, pasture, and patches of forest or woodlots. At the time sampling was conducted, the water level in the stream was very low, often appearing as stagnant or non-flowing. The substrates were primarily mud, sand, and gravel.

BIG CREEK (CR)
(Appendix 4, Map 41)

Of seven sites sampled in the Big Creek watershed, five were classified as semi-polluted, and one each as unbalanced and polluted. *Physa* and Chironomidae were the predominant organisms collected, comprising 24% and 23%, respectively. Stream substrates included sand in combination with mud, gravel, and debris. The adjacent watershed was primarily agricultural with row crops and pasture predominating.

Two point sources were located in the Big Creek watershed, both wastewater treatment plants serving Altamont. One, on an unnamed tributary, degraded the downstream area and was probably responsible for the semi-polluted condition of Big Creek upstream of Coon Creek. The second point source, located on Coon Creek, resulted in the semi-polluted condition observed on that tributary.

GREEN CREEK (CS)
(Appendix 4, Map 40)

Two unbalanced sites were sampled in Green Creek. The only point source was the Siegel wastewater treatment plant which was not discharging at the time of sampling. In addition, the receiving stream was dry. The predominant organisms collected were Chironomidae (30%) and *Physa* (18%). Principal substrate materials included sand, gravel, and mud. The adjacent watershed was agricultural.

WEST BRANCH (CT)
(Appendix 4, Map 39)

Five stations were sampled in the West Branch watershed, 80% of which were classified as unbalanced and 20% as balanced. Aquatic and semi-aquatic Heteroptera and Decapoda were the predominant organisms collected, each comprising 19% of the total organisms collected. In general, the stations were represented by nine to 10 taxa, with intolerant taxa usually comprising approximately 25% of the organisms and facultative ones, 45%. Sand and mud were the primary substrate materials and flow was quite low at the time of sampling. The adjacent watershed was primarily agricultural.

The only discharge located in this watershed was the Stewardson Strasburg High School which was not discharging during the summer, the time of sampling.

BUSH CREEK (CU)
(Appendix 4, Map 39)

Only two stations were sampled in Bush Creek and both were classified as unbalanced. *Physa* was the most common organism, comprising 33% of the individuals collected. Aquatic and semi-aquatic Heteroptera were also abundant, comprising 24% of all individuals taken. Both stations sampled were located approximately 0.5 mi upstream of Lake Mattoon on separate tributaries. The substrates at both sites were primarily sand mixed with mud and debris. At the time of sampling the stream bottom was covered with thick algal mats. Although no point sources were located in this watershed, drain tiles from the surrounding agricultural fields were present at these sites and would discharge into the streams when the water table was high or during the spring rainy season.

SMALL DIRECT TRIBUTARIES OF THE LITTLE WABASH RIVER (CZ)
(Appendix 4, Maps 39, 40, 41, 43, 44, 47, 48, 49, 50, and 55)

Thirty-seven stations were sampled on 23 small, direct tributaries of the Little Wabash River. Of these, 38% were classified as unbalanced, 59% as semi-polluted, and 3% as polluted. Substrates were usually sand mixed with silt and/or gravel. There was an uneven distribution of organisms among the four tolerance status groups with facultative and tolerant taxa comprising 81% of the organisms collected. Predominant organisms included aquatic Coleoptera (15%), Chironomidae (13%), aquatic and semi-aquatic Heteroptera (13%), and *Physa* (12%). The adjacent watersheds of these small tributaries were primarily agricultural.

Of the point sources actually discharging at the time of sampling, the Crossville, Neoga, and Clay City wastewater treatment plants degraded water quality in the receiving stream immediately downstream from their respective outfalls. At the Neoga plant, the stream had recovered to be classified as unbalanced by the time the stream had flowed one mile downstream. The stream classification changed from unbalanced upstream of the Clay City outfall to semi-polluted downstream. The Rushco Shell at Edgewood cannot be evaluated adequately as the receiving stream was dry upstream from this outfall. However, as the flow immediately downstream was derived from this discharge, the stream classification of semi-polluted immediately downstream is not considered poor under the circumstances.

EFFECTS OF OIL POLLUTION

Water samples analyzed for chloride were taken from approximately 500 stations in the Wabash River basin to assist in determining what, if any, effect the presence of oil well operations (pumping, storing, etc.) had upon stream quality. Brine introductions to surface waters are a common water quality problem in oil field areas. It was hoped that these analyses, summarized in Appendix 5 (performed by Illinois Environmental Protection Agency personnel), would pinpoint some of these potential problem areas. Some sites were revisited after several months to determine if the effects of the more obvious oil pollution problems had been reduced.

Nearly all chloride concentrations observed were 200 mg/l or less with the majority less than 50 mg/l. As many of these samples, especially those in the upper portion of the basin, were taken during summer drought, concentrations could be expected to be higher as water levels dropped. In general, however, concentrations were quite variable with little or no pattern either among major watersheds, within a stream system, or even among various sites within a stream.

Stations where concentrations exceeded 250 mg/l were double-checked to determine, if possible, the reason for an observed high chloride concentration. Of the nearly 500 samples analyzed, only 38 exceeded 250 mg/l. Of these, many could be an artifact of sampling during periods of very low water levels. Reviewing field data sheets revealed that very often these streams were becoming discontinuous and the water was only two or three inches deep. Also, because this is a rich oil-containing watershed, background concentrations might naturally be higher.

Stations for which chloride concentrations exceeded 250 mg/l, but for which no evidence of oil pollution or production existed, were not included in Table 8, which summarizes the stations where either crude oil was seen, active wells or storage areas were in the adjacent watersheds, or oil was observed either as a film on the surface of the water or in the substrate. Thus, many stations were not considered after reviewing the field data sheets. Generally, these were sites that occurred immediately downstream from a wastewater outfall where little or no dilution water existed or at stream sites where flow was reduced to several small, isolated pools.

Several problem areas, however, were observed. These included the following watersheds:

Crawfish Creek (BZJ); Wabash County; near Allendale; Map 52
 Raccoon Creek (BZK); Wabash County; near Allendale; Map 52
 Indian Creek (BEZB); Lawrence County; near Bridgeport; Maps 32, 33
 Little Vermilion River (BOZ); Vermilion River; near Georgetown;
 Map 12
 Dry Fork (CAJ); Wayne County; near Sims; Map 61
 Sugar Creek (BF); Crawford County; near Palestine; Map 37
 Bonpas Creek (BC); Richland County; near Lancaster; Map 51
 Gowdy Creek (CAZA); White County; near Enfield; Maps 63, 64
 Pond Creek Drainage Ditch (CC); Wayne County; near Burnt Prairie;
 Map 49

Table 8. Stations in the Wabash River basin where either high chloride concentrations, crude oil, active oil wells or storage areas, or oil present in the stream were observed.

STATION NUMBER	STREAM	DATE	CHLORIDE (mg/l)	STREAM CLASSIFICATION	CRUDE OIL PRESENT	ACTIVE OIL WELLS OR STORAGE	OIL PRESENT ON WATER OR IN SUBSTRATE	AGRICULTURAL WATERSHED

Little Muddy Creek (CJA); Clay County; near Sailor Springs; Map 44
Little Salt Creek (CPA); Effingham County; near Watson; Maps 41, 42

High chloride concentrations were not a reliable indicator of the presence or absence of oil pollution. For example, chloride concentrations were high (580 to nearly 2,000 mg/l) in an unnamed tributary of Crawfish Creek (BZJZ) and oil was present in the sediments. Crude oil, however, occurred at sites in Raccoon Creek (BZK) with low concentrations of chloride (<125 mg/l). This inconsistency in chloride concentration in the presence or absence of oil pollution was consistent (Table 8). Chloride concentrations were just as likely to be low to moderate in the presence of gross to light oil pollution as not.

STREAM SITES SAMPLED AND/OR
VISITED IN THE WABASH RIVER BASIN

STATION NUMBER	LOCATION	SAMPLING DATE	STREAM CLASSIFICATION
B-04	Wabash River, 1.8 mi SSE Grayville, upstream of RR bridge & I-64, White County, Illinois, T3S, R14W, SW $\frac{1}{4}$, SE $\frac{1}{4}$, Sec. 28 (New Harmony Quad)	09/14/77	Semi-Polluted
B-16	Wabash River, 2.4 mi ESE New Haven, 0.4 mi downstream of Little Wabash River, Gallatin County, Illinois, T7S, R10E, NE $\frac{1}{4}$, SW $\frac{1}{4}$, NE $\frac{1}{4}$, Sec. 27 (Emma Quad)	09/15/77	Semi-Polluted
B-17	Wabash River, 1.7 mi ESE New Haven, 0.5 mi upstream of Little Wabash River, White County, Illinois, T7S, R10E, E $\frac{1}{2}$, NW $\frac{1}{4}$, SW $\frac{1}{4}$, Sec. 22 (Emma Quad)	09/15/77	Semi-Polluted
B-18	Wabash River, 0.4 mi W New Harmony, 0.25 mi downstream US 460 bridge, White County, Illinois, T4S, R14W, SE $\frac{1}{4}$, SW $\frac{1}{4}$, SE $\frac{1}{4}$, Sec. 35 (New Harmony Quad)	09/14/77	Semi-Polluted
B-19	Wabash River, 0.7 mi E Grayville, 0.7 mi upstream of Bonpas Creek, Wabash County, Illinois, T3S, R14W, S $\frac{1}{2}$, NE $\frac{1}{4}$, Sec. 21 (Grayville Quad)	09/14/77	Semi-Polluted
B-20	Wabash River, 3.5 mi SSW Mt. Carmel, upstream of RR bridge, Wabash County, Illinois, T2S, R12W, NE $\frac{1}{4}$, SE $\frac{1}{4}$, Sec. 6 (Kennsburg Quad)	09/14/77	Semi-Polluted
B-21	Wabash River, 1.3 mi SE Mt. Carmel, upstream of IL 15, downstream RR bridge, Wabash County, Illinois, T1S, R12W, N $\frac{1}{2}$, SW $\frac{1}{4}$, Sec. 28 (Mt. Carmel Quad)	09/13/77	Semi-Polluted
B-22	Wabash River, 0.4 mi E St. Francisville, upstream St. Francisville wastewater treatment lagoon, E of park, Lawrence County, Illinois, T2N, R11W, SW $\frac{1}{4}$, SW $\frac{1}{4}$, NE $\frac{1}{4}$, Sec. 21 (St. Francisville Quad)	09/13/77	Semi-Polluted
BB-10	French Creek, 3 mi NW Grayville, Edwards County, Illinois, T2S, R14W, NE $\frac{1}{4}$, SW $\frac{1}{4}$, SW $\frac{1}{4}$, Sec. 31 (Albion South Quad)	08/16/77	Semi-Polluted
BBA-10	Onion Creek, 2 mi WNW Grayville, Edwards County, Illinois, T3S, R11E, NE $\frac{1}{4}$, SE $\frac{1}{4}$, NE $\frac{1}{4}$, Sec. 18 (Albion South Quad)	08/16/77	Semi-Polluted
BC	Bonpas Creek, 4 mi S Claremont, Richland County, Illinois, T3N, R14W, SE $\frac{1}{4}$, SE $\frac{1}{4}$, NE $\frac{1}{4}$, Sec. 29 (Claremont Quad)	06/07/77	Dry
BC-11	Bonpas Creek, 5 mi W Lancaster, Richland County, Illinois, T2N, R14W, NW $\frac{1}{4}$, SW $\frac{1}{4}$, SE $\frac{1}{4}$, Sec. 27 (Berryville Quad)	06/10/77	Unbalanced
BC-12	Bonpas Creek, 1.6 mi W Berryville, Richland County, Illinois, T2N, R14W, SW $\frac{1}{4}$, SE $\frac{1}{4}$, SW $\frac{1}{4}$, Sec. 15 (Berryville Quad)	06/07/77	Unbalanced
BCA-10	Indian Creek, 2.3 mi S Bone Gap, Edwards County, Illinois, T1S, R14W, SW $\frac{1}{4}$, SW $\frac{1}{4}$, NW $\frac{1}{4}$, Sec. 20 (Albion North Quad)	07/13/77	Unbalanced
BCBZ	Unnamed tributary Fordice Creek, 2 mi E Gards Point, Wabash County, Illinois, T1N, R14W, SW $\frac{1}{4}$, SW $\frac{1}{4}$, NW $\frac{1}{4}$, Sec. 33 (Mt. Carmel Quad)	06/08/77	Dry
